EXECUTIVE SUMMARY

In 1977, Congress passed amendments to the Clean Air Act (CAA) with the goal of improving visibility in Class I federal areas, such as national parks and wilderness areas. Following the enactment of the 1977 CAA amendments, some measures were taken to address issues such as “plume blight” from specific pollution sources, but little was done to improve the regional haze issues in the Eastern United States. Congress passed additional amendments to the CAA in 1990 that authorized additional research and regular progress updates.

The U.S. Environmental Protection Agency (EPA) adopted the federal Regional Haze Rule on July 1, 1999. The Regional Haze Rule and the CAA require consultation between the states, tribes and the Federal Land Managers (FLMs) for managing Class I areas. Since regional haze often results from pollution emitted across broad regions, this multi-state planning effort will help in developing the most cost-effective controls for regional haze. This consultation process will provide a coordinated effort to achieve the federal visibility requirements and aid in developing regional strategies for meeting progress goals.

The Regional Haze Rule went into effect on August 30, 1999. The EPA selected five Regional Planning Organizations (RPOs) to aid in the coordination required to achieve the national visibility goals of Class I areas by 2064. One RPO, the Central Regional Air Planning Association (CENRAP), is comprised of nine states that make up the midsection of the contiguous United States, including Missouri. Missouri has two federal Class I areas (Hercules Glades and Mingo) within its borders and is in close proximity with two Class I areas in Arkansas (Caney Creek and Upper Buffalo).

Between 2000 and 2007, Missouri participated in the CENRAP workgroup process to develop technical analyses and control strategies for the Regional Haze Plan. Missouri determined the baseline visibility conditions for each Class I area using monitoring data collected from 2000 through 2004 and compared them to the natural background conditions. The technical analyses showed that both of the Class I areas in Missouri will meet the 2018 Reasonable Progress Goal (RPG). The analyses in this Regional Haze Plan demonstrate that the 2018 visibility goals for

Mingo and Hercules Glades will be largely achieved from EGU (Electric Generating Unit) emission reductions resulting from the federal Clean Air Interstate Rule (CAIR) program. Missouri long-term strategy also consists of other air pollution programs including Missouri NO_X State Implementation Plan (SIP) call, Tier 2 vehicle emission standards, other states' SIP controls, other states' Best Available Retrofit Technology (BART) controls, as well as other programs. Additional controls not included in the RPG modeling demonstration are also identified in the long-term strategy chapter of the plan and may be considered during the five-year review.

Missouri has satisfied the consultation requirement of the federal Regional Haze Rule through the consultation process that was used to develop this plan. The consultation process is documented in a consultation plan that was used to attain and share the technical information necessary in developing this Regional Haze Plan for the Central Class I areas. A copy of the consultation plan has been provided as an appendix to this plan. In addition, Missouri has consulted with and continues to consult with other states that have included Missouri in their consultation process to meet their Regional Haze Rule requirements.

A BART analysis was used to assure that the federal Regional Haze Rule requirements were met. This analysis included BART source development, screen-modeling analyses and refined modeling. As a result of the analysis and modeling, Missouri has identified one BART-eligible source in Missouri that must undergo a BART control evaluation to ensure it meets the Regional Haze Rule requirements.

The Missouri Department of Natural Resources (department) Air Pollution Control Program will submit this Regional Haze Plan to the EPA for inclusion in the Missouri SIP to meet the requirements of EPA's Regional Haze Rule. A public hearing was held for this plan on December 6, 2007, and the plan was adopted by the Missouri Air Conservation Commission (MACC) on February 7, 2008. A public hearing was held for a revision to this plan on June 25, 2009, and the revised plan was adopted by the MACC on July 29, 2009.

Missouri will continue to coordinate with other states, FLMs, EPA, CENRAP, and other RPOs to

maintain/improve the visibility in Missouri's Class I areas. This coordination will include five-year progress reports and any necessary SIP revisions. If deemed necessary, there will be face to face consultation meetings.

1.0 BACKGROUND - FEDERAL REGIONAL HAZE REGULATION

1.1 FEDERAL REGIONAL HAZE RULE

In amendments to the CAA in 1977, Congress added Section 169 (42 U.S.C. 7491), setting forth the following national visibility goal of restoring pristine conditions in national parks and wilderness areas:

> *Congress hereby declares as a national goal the prevention of any future, and the remedying of any existing, impairment of visibility in mandatory Class I Federal areas which impairment results from man-made air pollution.*

Over the following years, modest steps were taken to address the visibility problems in Class I areas. The control measures taken mainly addressed plume blight from specific pollution sources and did little to address regional haze issues in the Eastern United States. Plume blight is the visual impairment of air quality that manifests itself as a coherent plume. This results from specific sources, such as a power plant smokestack, emitting pollutants into a stable atmosphere. The pollutants are then transported in some direction with little or no vertical mixing.

When the CAA was amended in 1990, Congress added Section 169B (42 U.S.C. 7492), authorizing further research and regular assessments of the progress made so far. In 1993, the National Academy of Sciences concluded that "current scientific knowledge is adequate and control technologies are available for taking regulatory action to improve and protect visibility."[1]

In addition to authorizing creation of visibility transport commissions and setting forth their duties, Section 169B(f) of the CAA specifically mandated creation of the Grand Canyon Visibility Transport Commission (GCVTC) to make recommendations to the EPA for the region affecting the visibility of the Grand Canyon National Park. Following four years of research and policy development, the GCVTC submitted its report to EPA in June 1996. This report, as well

1 National Research Council. *Protecting Visibility in National Parks and Wilderness Areas*. National Academy Press. Washington, DC: 1993.

as the many other research reports prepared by the GCVTC, contributed invaluable information to EPA in its development of the federal Regional Haze Rule.

EPA's Regional Haze Rule was adopted July 1, 1999, and went into effect on August 30, 1999. The Regional Haze Rule aimed at achieving national visibility goals by 2064. This rulemaking addressed the combined visibility effects of various pollution sources over a wide geographic region. This broad scope meant that many states – even those without Class I areas – would be required to participate in haze-reduction efforts. EPA designated five RPOs to assist with the coordination and cooperation needed to address the visibility issue. Those states that make up the midsection of the contiguous United States were designated as CENRAP.

On May 24, 2002, the U.S. Court of Appeals, D.C. District Court ruled on the challenge brought by the American Corn Growers Association against EPA's Regional Haze Rule of 1999. The Court remanded to EPA the BART provisions of the rule and denied the industry's challenge to the haze rule goals of natural visibility and no degradation. EPA has proposed revisions to the Regional Haze Rule pursuant to the remand. To facilitate the review of this SIP submittal by the EPA, FLMs, stakeholders, and the public; a guide is provided in 40 CFR 51.308, *Regional Haze Program Requirements* (Appendix A).

1.2 CLASS I AREAS

The State of Missouri has the following Class I areas within its borders:

Hercules Glades Wilderness Area

Situated in southwest Missouri, Taney County, Hercules Glades Wilderness Area (Hercules Glades) is managed by the United States Department of Agriculture (USDA) Forest Service as part of the Mark Twain National Forest. The area includes 12,315 acres located in some of the most rugged hills of the Missouri Ozarks. The closest urban area is the Springfield/Branson metropolitan statistical area, 40 miles to the west/northwest.

Mingo National Wildlife Refuge

The Mingo National Wildlife Refuge (Mingo) is managed by the U.S. Fish and Wildlife Service. The refuge is situated in southeast Missouri, along the Mississippi Flyway. Only a portion of the

refuge is a Class I area (7,730 acres of a total 21,676 acres). Memphis to the south and St. Louis to the north are some of the largest urban areas nearby, although there are a few smaller population centers mostly to the east. Proximity to sources in the Ohio River Valley is a consideration.

In accordance with 40 CFR 51.308, Missouri has identified emissions sources within Missouri that have or may have impacts on the following Missouri Class I areas: Hercules Glades and Mingo. Emissions from Missouri may also contribute to visibility impairment in other states' Class I areas, such as the Caney Creek and Upper Buffalo Wilderness Areas in Arkansas (Upper Buffalo).

Improved visibility will lead to greater enjoyment of recreational opportunities at Hercules Glades and Mingo. The tourists drawn to the scenic beauty and recreational opportunities of each of these areas provide revenue to the respective regions. Missouri expects improved visibility of Hercules Glades and Mingo to provide not only enhanced scenic beauty, but also improved health benefits for people who are more susceptible to respiratory problems.

2.0 GENERAL PLANNING PROVISIONS

2.1 PLAN SUBMISSION

Pursuant to the requirements of 51.308(a) and (b), this Missouri Regional Haze Plan is being submitted for inclusion into the SIP as adopted to meet the requirements of EPA's Regional Haze Rule that was implemented to comply with requirements set forth in the CAA. Elements of this plan address the core requirements pursuant to 40 CFR 51.308(d) and the BART components of 40 CFR 50.308(e). In addition, this plan addresses regional planning; state/tribe and FLM coordination; and contains a commitment to provide plan revisions and adequacy determinations. Missouri has adopted this plan submittal in accordance with state laws and rules.

2.2 LEGAL AUTHORITY

The MACC is granted the legal authority to develop and implement regulations regarding air pollution under section 643.050 of the Revised Statues of Missouri.

2.3 PUBLIC HEARING NOTICE AND CERTIFICATION

The department's Air Pollution Control Program is required to announce a public hearing at least 30 days prior to holding such a hearing. Announcements were submitted to newspapers at least 30 days prior to the public hearing. The public hearing for this Regional Haze Plan occurred on December 6, 2007 and the public hearing for the revision to the plan occurred on June 25, 2009. Attached in Appendix B are the public hearing notices, along with certification of publication of the public notices for the Regional Haze Plan public hearings.

2.4 COMMENTS, RESPONSES, AND EXPLANATIONS OF CHANGE

Attached in Appendix C are the department's Air Pollution Control Program responses to comments received during the open public comment periods for this region haze plan. The comment period on the Regional Haze Plan was open until December 13, 2007, seven days after the Public Hearing that was held on December 6, 2007. The comment period on the revision to the Regional Haze Plan was open until July 2, 2009, seven days after the Public Hearing that was held on June 25, 2009. The department's Air Pollution Control Program is required to respond

to all comments received by either amending the plan or explaining the reasoning for not making an amendment.

2.5 MISSOURI AIR CONSERVATION COMMISSION ADOPTION CERTIFICATION

Attached in Appendix D are the MACC adoption certifications to demonstrate the approval of the Regional Haze Plan by the Commission.

2.6 COMMITMENT TO REVISE PLAN

Consultation between the states and the FLMs will continue as the federal regional haze program progresses. The consultation will continue via participation in CENRAP, and if CENRAP is no longer operating, Missouri will lead the consultation with other states and FLMs for meeting Missouri's goals. This effort will include five-year progress reports and development and review of any plan revisions deemed necessary. It will also provide for consideration of any other programs that are implemented and have the potential to contribute to impairment of visibility in Class I areas.

3.0 REGIONAL PLANNING

In 1999, EPA and affected states/tribes agreed to create five RPOs to facilitate interstate coordination on regional haze plan submittals and Tribal Implementation Plans (TIPs). Figure 3.1 shows a map of all five RPOs. The State of Missouri is a member of the CENRAP RPO. Members of CENRAP include the following states: Arkansas, Iowa, Kansas, Louisiana, Minnesota, Missouri, Nebraska, Oklahoma, and Texas.

Figure 3.1: Geographical Areas of Regional Planning Organizations

The governing body of CENRAP is the Policy Oversight Group (POG). The POG is made up of 18 voting members representing the states and tribes within the CENRAP region and non-voting members representing local agencies, the EPA, the Fish and Wildlife Service, Forest Service and National Park Service. The POG facilitates communication with FLMs, stakeholders, the public, and CENRAP staff.

Since its inception, CENRAP has established an active committee structure to address both technical and non-technical issues related to regional haze. The work of CENRAP is

accomplished through five standing workgroups: Monitoring; Emission Inventory; Modeling; Communications; and Implementation and Control Strategies. Participation in workgroups is open to all interested parties. Ad hoc workgroups may be formed by the POG to address specific issues. Ultimately, the CENRAP POG makes policy decisions.

CENRAP has adopted the approach that the Regional Haze Rule requires the "States to establish goals and emission reduction strategies for improving visibility in all 156 mandatory Class I parks and wilderness areas." The rule also encouraged states and tribes to work together in regional partnerships.

This plan utilizes data analysis, modeling results and other technical support documents prepared for CENRAP members. By coordinating with CENRAP and other RPOs, Missouri has worked to ensure that its long-term strategy provides sufficient reductions to mitigate impacts of sources from Missouri on affected Class I areas. Data analyses, modeling results and other technical support documents are provided to CENRAP members through either CENRAP's website or through a file transfer protocol (ftp) that allows users to copy files between their local system and CENRAP's system that they can reach on the CENRAP network.

4.0 PLAN COORDINATION AND CONSULTATION

4.1 CENTRAL CLASS I AREAS CONSULTATION

40 CFR 51.308(i) requires coordination between states/tribes and the FLMs. FLMs are an integral part of CENRAP's POG and the membership on standing committees. FLMs have contributed to the development of technical and non-technical work as a result of that participation. In addition, opportunities have been provided by CENRAP for FLMs to review and comment on each of the technical documents developed by CENRAP and included in this plan. Missouri has provided agency contacts to the FLMs as required. In development of this plan, the FLMs were consulted in accordance with the provisions of 51.308(i)(2).

Missouri provided FLMs an opportunity for consultation and an opportunity to hold a face to face meeting, if deemed necessary. All of the consultation for this plan was conducted by conference call with no need expressed for a face to face meeting and a draft of the plan was provided at least 60 days prior to holding the public hearing on the Regional Haze Plan.

During the consultation process, the FLMs were given the opportunity to address their:

- Assessment of the impairment of visibility in any Class I areas
- Recommendations on the development of RPGs
- Recommendations on the development and implementation of strategies to address visibility impairment.

According to 40 CFR 51.308(d)(3)(i), Missouri is required to consult with other states/tribes to develop coordinated emission strategies. This requirement applies both when emissions from the state are reasonably anticipated to contribute to visibility impairment in Class I areas outside the state and when emissions from other states/tribes are reasonably anticipated to contribute to visibility impairment in Class I areas within the state.

Missouri has consulted with other states/tribes in CENRAP, Visibility Improvement State and Tribal Association of the Southeast (VISTAS), the Midwest Regional Planning Organization (MRPO), FLMs and EPA Regions 5, 6 and 7 on development of coordinated strategies for

Central Class I areas, including Mingo, Hercules Glades, Upper Buffalo, and Caney Creek. Technical analyses, such as Area of Influence (AOI) and source apportionment, were developed as part of consultation planning to determine contributing states (Appendix E).

Missouri provided the Regional Haze Plan to the FLMs for review on August 23, 2007 and notified the FLMs that a public hearing would be held on this plan at a later date. The FLMs provided early comments on the draft plan and a conference call between Missouri, FLMs, and EPA Region 7 was conducted on September 25, 2007 to discuss the comments. Missouri considered all comments the FLMs provided on the early draft of the plan.

Regional modeling and other findings were used to develop RPGs for the Arkansas and Missouri Class I areas based on the existing and proposed controls through both state and federal requirements. It was also determined that these RPGs will meet the established URP goals by 2018. The consultation process determined which states significantly impacted the Arkansas and Missouri Class I areas.

Missouri is reasonably anticipated to contribute to the following Class I areas:

1) Mingo National Wildlife Refuge, Missouri
2) Hercules Glades Wilderness, Missouri
3) Upper Buffalo Wilderness Area, Arkansas
4) Caney Creek Wilderness Area, Arkansas

The state's coordination with FLMs on long-term strategy development is described in Chapter 11. The consultation was completed based on a determination that reasonable progress was achieved by contributing states.

4.2 OTHER STATE CONSULTATIONS

The consultation processes for the Wichita Mountains (WIMO) Class I area in Oklahoma was completed prior to the March 2008 submittal of this plan. The Oklahoma Department of Environmental Quality indicated their belief that Missouri sources impact WIMO. However, in response to the Oklahoma consultation letter, Missouri replied with a letter recommending that the rationale for determining contributing states deserves further examination. A more inclusive

methodology for the Central Class I areas with four different metrics (Particulate Matter Source Apportionment Technology (PSAT), PMF, AOI, and emission rate divided by five times the distance - Q/d) was used in a combined manner with three out of four positive results required before concluding that a particular state is contributing. The distance between WIMO and western Missouri's Class I area is approximately 200-250 miles farther west. Because of this distance, it is counter-intuitive to assume that planned emission controls on Missouri sources would be significant enough. It seems likely that Missouri would not be included as significant based on this level/type of PSAT analysis, and emissions/source distance ratio.

It is also not clear that additional controls in Missouri would be reasonable to reduce the visibility in WIMO. Based on the PSAT analysis presented, over half the elevated point-source impacts to WIMO are due to sources in Oklahoma, Texas, and Louisiana and most of the area source impacts are due to Oklahoma and Texas sources. Point and area are the two largest emission sectors. Controls appear likely to be more efficient in those states, on a cost-per-ton basis, than additional controls in Missouri.

Consultation processes for the Minnesota Class I areas was also conducted prior to the March 2008 submittal of this plan. The Minnesota Pollution Control Agency indicated that it believes that Missouri impacts the Boundary Waters, but not Voyageurs.

Minnesota identified Missouri as a contributing state based on LADCO 2002-2003 Trajectory analysis or LADCO 2018 PSAT modeling analysis at over a 5 percent total contribution to haze at either of their Class I areas. The criteria are met marginally at 5.2 percent for 2018 PSAT for the Boundary Waters area only.

Analysis conducted as part of the Causes of Haze II Study[2] shows emissions for the northern Class I area at Voyageurs National Park indicating the high impact of Minnesota sources, with

[2] Causes of Haze II, 2005; Sullivan, Hafner, Brown, MacDonald, Raffuse, Penfold, Roberts, Sonoma Technology

only small impact by out of state sources. Voyageurs and the Boundary Waters are very close in proximity, and the overall analysis was intended to apply regionally. The Emission Impact Potential mappings below underscore the impact of Minnesota sources on the area, and how controls on a relative few will provide much greater result than controls on sources outside Minnesota. Comparisons with Hercules Glades EIP show the difference in areas with significant external sources (Hercules) to areas with significant internal sources (Voyageurs, Boundary Waters). The conclusion reached in the Causes of Haze II is that for Voyageurs, and by geographic proximity, Boundary Waters, important emission source regions are internal (Minnesota and to a lesser extent North Dakota) on the 20 percent worst days. Area of Influence analysis for CENRAP states confirms that Level I Sulfate for both areas barely enters the northwest 20 miles of Missouri, not indicating strong source influence.

The most recent CENRAP PSAT analysis, as Figure 4.3, shows most Minnesota anthropogenic sources with very high impacts on Boundary Waters, slightly more than 15 inverse megameters for 2002. For 2018 modeling, it remains at almost 14 inverse megameters. Of other states, only Wisconsin elevated point impacts are larger than 2 inverse megameters, and Missouri impacts are 1.6. Based on the AOI and PSAT analyses, it is not reasonable to control the Missouri sources at the same level as Minnesota sources to achieve a very small impact at the Boundary Waters Class I area.

Missouri provided a written response to Minnesota regarding the Northern Class I Areas consultation.

Since other states are still involved in their consultation process for their respective plans, Missouri will continue to participate in their consultation processes, as necessary.

5.0 ASSESSMENT OF BASELINE AND CURRENT CONDITIONS AND ESTIMATE OF NATURAL CONDITIONS

5.1 VISIBILITY REQUIREMENTS

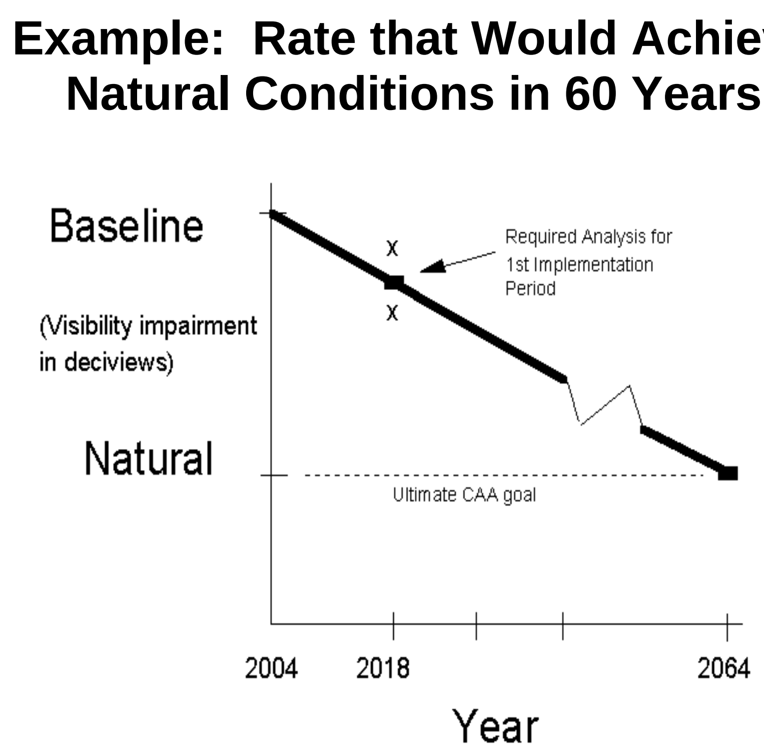
The goal of the Regional Haze Rule is to restore natural visibility conditions to the 156 Class I areas identified in the 1977 CAA Amendments. Sec. 51.301(q) defines natural conditions: "Natural conditions includes naturally occurring phenomena that reduce visibility as measured in terms of light extinction, visual range, contrast, or coloration." The regional haze plans must contain measures that make "reasonable progress" toward this goal by reducing anthropogenic emissions that cause haze. For each Class I area, there are three metrics of visibility that are part of the determination of reasonable progress:

1) baseline conditions
2) natural conditions
3) current conditions

Each of the three metrics includes the concentration data of the visibility pollutants as different terms in the light extinction algorithm, with respective extinction coefficients and relative humidity (RH) factors. Total light extinction when converted to deciviews (dv) is calculated for the average of the 20 percent best and 20 percent worst visibility days.

"Baseline" visibility is the starting point for the improvement of visibility conditions. It is the average of the Interagency Monitoring and PROtected Visual Environments (IMPROVE) monitoring data for 2000 through 2004 and can be thought of as "current" visibility conditions for this initial period. The comparison of initial baseline conditions to natural visibility conditions indicates the amount of improvement necessary to attain natural visibility by 2064. Natural visibility is determined by estimating the natural concentrations of visibility pollutants and then calculating total light extinction with the light extinction algorithm (Figure 5.1). Each state must estimate natural visibility levels for Class I areas within its borders in consultation with FLMs and other states (51.308(d)(2)). "Current conditions" are assessed every five years as part of the plan review where actual progress in reducing visibility impairment is compared to the reductions committed to in the plan (Appendix F, Chapter 4.0).

Figure 5.1: Determination of Natural Background



Consultation regarding the visibility metrics

Consultation among states is a requirement that is repeated in the Regional Haze Rule. As part of a "long-term strategy" for regional haze, a state whose emissions are "reasonably anticipated" to contribute to impairment in other states' Class I area(s) must consult with those states and also consult with any states whose emissions affect its own Class I area(s) (sec. 51.308(d)(3)).

A chief purpose of the RPO is to provide a means for states to confer on all aspects of the regional haze issue, including consultation on reasonable progress goals and long-term strategies, which are based on the current (baseline) and natural visibility determinations. This process is described in Chapter 3, *Regional Planning*. CENRAP has provided a forum for the member states and tribes to consult on the determination of baseline and natural visibility conditions in each of the Class I areas.

In addition, states in CENRAP have conferred with neighboring Class I area states outside CENRAP, both individually and by way of the states' RPO.

Sec. 51.308(i) requires Class I area states' coordination with FLMs that includes consultation on implementation, including the assessment of visibility impairment and recommendations regarding the reasonable progress goal and strategies for improvement.

Through participation in CENRAP and as a state, Missouri has completed this regulatory requirement. Details of actions taken to meet this requirement are found in the *Central Class I Areas Consultation Plan* (Appendix E).

5.2 BASELINE VISIBILITY CONDITIONS

During the five-year (2000-2004) baseline period, sites are required to have three valid years of data from which baseline conditions can be constructed. The Visibility Information Exchange Websystem (VIEWS) website (http://vista.cira.colostate.edu/views/) has posted particulate matter (PM)-species specific natural and baseline conditions based on the new IMPROVE algorithm. The new IMPROVE algorithm was developed by fitting reconstructed light extinction based on IMPROVE measured PM and nitrite (NO_2) concentrations with actual co-located measured light extinction (e.g., nephelometer measurements. The VIEWS document, *Revised IMPROVE Algorithm for Estimating Light Extinction from Particle Speciation Data*, posted under gray literature, explains the justification for the use of the new equation. Section II of this algorithm document, which provides more detail on the revised IMPROVE equation is included as Appendix G. The choice between use of the default or the refined equation for calculating the visibility metrics for each Class I area is made by the state in which the Class I area is located.[3] It is with these calculations that the state develops a RPG for each Class I area, in consultation with other states whose emissions affect visibility in that park or wilderness area (sec. 51.308(d)(1)(iv)).

Because it is based on more recent science which better exemplifies the observed light extinction values, Missouri, as well as other CENRAP states, has elected to perform their primary visibility

[3] According to sec. 51.308(d)(2), the state will make the determinations of baseline and natural visibility conditions.

projections using the new IMPROVE equation to calculate visibility metrics for the purpose of developing its reasonable progress goal (Appendix F, Section 4.2.1.1.3).

Using these PM-species specific natural conditions and the curved extinction glidepaths, we can evaluate how well visibility extinction achieves the 2018 Uniform Rate of Progress (URP) goal on a species-by-species basis in accordance with 40 CFR 51.308(d)(2).

The Mingo Class I area has an established baseline visibility of 13.76 dv for the cleanest 20 percent of the sample days and 28.02 dv for the 20 percent worst visibility days, as indicated in Table 5.1. This is based on sampling data collected at the Mingo IMPROVE monitoring site, which was established by the IMPROVE sampling staff at the University of California-Davis via their protocols. For Mingo, because of a clogged Module C Inlet, carbon data was not available from June 2000 to January 2002. The resolution was a substitution protocol developed by Warren White using organic mass hydrogen (OMH) to develop a surrogate for organic mass carbon (OMC). Data filling was used to obtain sufficient data so that three-years of valid data were available from which baseline conditions could be calculated. The data filled IMPROVE database were prepared and made available on the VIEWS website, where more information on the data filling procedures can be found (http://vista.cira.colostate.edu/views/).

The Hercules Glades Class I area has an established baseline visibility of 12.84 dv for the cleanest 20 percent of the sample days and 26.75 dv for the 20 percent worst visibility days. This is based on sampling data collected at the Hercules Glades IMPROVE monitoring site which was established by the IMPROVE sampling staff at the University of California-Davis via their protocols.

Table 5.1: Baseline Visibility Conditions for Missouri Class I Areas

Baseline Visibility Conditions 2000-2004		
Class 1 Area	**Average for 20% Worst Days (dv)**	**Average for 20% Best Days (dv)**
Mingo	28.02	13.76
Hercules Glades	26.75	12.84

5.3 NATURAL VISIBILITY CONDITIONS

EPA's "Guidance for Estimating Natural Visibility Conditions Under the Regional Haze Program" (Sept 2003) provides states a "default" estimate of natural visibility. The default values of concentrations of visibility pollutants are based on a 1990 National Acid Precipitation Assessment Program report (Trijonis, J.C. 1990). In the guidance, the United States is divided into "East" and "West" along the western boundary of the states one tier west of the Mississippi River. This division divides the CENRAP states into "East" (MN, IA, MO, AR, and LA), with seven Class I areas, and "West" (NE, KS, OK, and TX), with three Class I areas. In the two equations, only sulfate (SO_4) and organic carbon have different values, but the calculated dv difference is significant (see Appendix F, Section 4.2 for further discussion of the default equation).

Using the New IMPROVE equation, Missouri has determined that natural visibility conditions for the Mingo Class I area is best represented by 12.40 dv for the 20 percent worst days (Table 5.2). The Hercules Glades Wilderness Class I area is best represented by 11.30 dv for the 20 percent worst days. Appendix F, Section 4.2.1.1.3 provides calculations, methodologies, and a discussion of the reasons for selection of the methodology and a demonstration of the appropriateness of these values for both Class I areas.

Table 5.2: Natural Background Conditions for the Class 1 Areas in Missouri

Class 1 area	20% Worst Days Goal (dv)	20% Best Days Goal
Mingo	12.40	No degradation
Hercules Glades	11.30	No degradation

6.0 MONITORING STRATEGY

6.1 MONITORING REQUIREMENTS

Section 51.308(d)(4) of the federal Regional Haze Rule requires a monitoring strategy for measuring, characterizing, and reporting regional haze visibility impairment that is representative of all mandatory Class I areas within the State of Missouri. The monitoring strategy relies upon participation in the IMPROVE network.

6.2 CURRENT MONITORING STRATEGY

Upon the creation of CENRAP, the newly formed Monitoring Workgroup identified large visibility data voids in Southern Arkansas, Iowa, Kansas, Southern Minnesota, Nebraska, and Oklahoma. Only five IMPROVE sites were located in the CENRAP region. Between 2000 and 2003, five more IMPROVE sites and 15 IMPROVE protocol sites were installed. In Missouri, IMPROVE Sites are located at Hercules Glades and Mingo (Figures 6.1 and 6.2). An IMPROVE protocol sampler is located at the site near El Dorado Springs (Figure 6.3). Missouri commits to meet the requirements under 40 CFR 51.308(d)(4)(iv) to report to EPA visibility data for each of Missouri's Class I areas annually.

The filter samples from the IMPROVE modules are sent for analysis to the Crocker Nuclear Laboratory of the University of California in Davis and the data is posted to the IMPROVE website and the VIEWS website.[4] Details regarding the monitors (location, date of installation, etc., and monitoring data) are found at the VIEWS website. This fulfills Missouri's reporting requirement of visibility data (electronic) under subsection (iv).

---

Figure 6.1: Hercules Glades IMPROVE Monitoring Station

Figure 6.2: Mingo IMPROVE Monitoring Station

Figure 6.3: El Dorado Springs IMPROVE Protocol Monitoring Station

6.3 FUTURE MONITORING STRATEGY

In order to assess progress in reducing visibility impairment in Class I areas, the existing IMPROVE and IMPROVE Protocol sites will be maintained contingent upon continued national funding to measure, characterize and report regional haze visibility impairment to satisfy requirements of subsection (i). If EPA elects to revise funding for this network, Missouri will evaluate the IMPROVE protocol site at El Dorado Springs. Any changes appropriate to continued monitoring of Regional Haze for the Missouri Class I areas will be evaluated during the Missouri five-year review. The five-year review will include the following aspects:

- QA IMPROVE data from Mingo and Hercules Glades.
- Calculate current visibility conditions for most impaired and least impaired days.
- Calculate differences between current conditions and baseline conditions.
- Determine whether RPGs are being met.

Missouri will also evaluate technology changes and the need for new monitors as appropriate.

6.4 SPECIAL MONITORING STUDIES

Special monitoring in the CENRAP region for ammonia was conducted from November 1, 2003 through June 28, 2006. In all, approximately 7,200 individual ammonia and associated measurements were attempted in the course of this project. One of the primary outcomes of this sampling was the disclosure that high concentrations of ammonia are occurring in the northern and central CENRAP regions with a considerable regularity. It seems likely that these are due to the agricultural sources that have been documented as emitters of ammonia, including animal raising and fertilizer application.[5]

(Champaign, IL): August 31, 2006. A copy of the report is available from David A. Gay, Associate Research Scientist, Illinois State Water Survey, University of Illinois, 217-244-0462.

7.0 EMISSIONS INVENTORY

7.1 2002 AND 2018 EMISSIONS INVENTORY SUMMARY

As specified in the EPA guidance document, *Emissions Inventory Guidance for Implementation of Ozone and Particulate Matter National Ambient Air Quality Standards (NAAQS) and Regional Haze Regulations* (August 2005), the regional haze emissions inventory includes carbon monoxide (CO), nitrogen oxides (NO_x), sulfur dioxide (SO_2), volatile organic compounds (VOCs), fine particulate ($PM_{2.5}$), coarse particulate (PM_{10}), and ammonia (NH_3). Missouri used the CENRAP Base G emissions inventory for both the baseline year of 2002 and future year of 2018. Tables 7.1 and 7.2 summarize the Missouri 2002 and 2018 inventories, respectively. Tables H.1-8 in Appendix H include the complete 2002 and 2018 emissions inventory for Missouri.

Table 7.1: 2002 Missouri Emissions Inventory Summary

Source Sector	NO_X (TPY*)	SO_2 (TPY)	PM_{10} (TPY)	$PM_{2.5}$ (TPY)	CO (TPY)	VOC (TPY)	NH_3 (TPY)

7.2 OVERVIEW OF EMISSIONS INVENTORY DEVELOPMENT

7.2.1 Point Sources

The 2002 point source inventory is based on information reported by facilities on Emission Inventory Questionnaires (EIQs). The 2002 EIQ data collection process was conducted by the department's Air Pollution Control Program and the local air pollution agencies of St. Louis County and the City of St. Louis. As the coordinating agency for point source inventory development, the department's Air Pollution Control Program performed the overall quality-assurance procedures and submitted the data to EPA's 2002 National Emissions Inventory (NEI) to meet the requirements of the CERR.

Following submission of the Missouri point source inventory to the 2002 NEI, additional quality assurance, and revision of the data was completed through the CENRAP process. E. H. Pechan & Associates (Pechan), through a contract with CENRAP, obtained the Missouri point source inventory and worked with the department's Air Pollution Control Program to make corrections where needed. In particular, an error that resulted in the double counting of emissions from a number of emission units was corrected. The problem affected VOC emissions only. For example, for the Chrysler-North facility (291890231), emission unit number 20949, which emitted a total of 112 tons/year (about 0.3 tons/day) VOC in 2002, was associated with stack numbers 44387 and 44388. Instead of being proportioned between the two stacks, the total amount of 112 tons/year was linked to each stack, which doubled the emissions. In all, this problem resulted in overstating VOC emissions in the St. Louis nonattainment area by a total of 751 tons/year (roughly 2 tons/day). Other revisions included corrections to facility coordinates and stack parameters. Pechan also converted the point source inventory to the Sparse Matrix Operator Kernel Emissions/Inventory Data Analyzer (SMOKE/IDA) format. Pechan's work is described in detail in the two documents included in Appendix H: *The Consolidation of Emissions Inventories* (April 28, 2005) and *Refinement of CENRAP's 2002 Emissions Inventories* (August 31, 2005).

The 2018 point source emissions inventory was prepared by CENRAP. For non-EGUs, the 2002 emissions were projected to 2018 by applying growth and control factors using the SMOKE

model. The growth and control factors were prepared by Pechan and are documented in the following report in Appendix H.4: *Development of Growth and Control Inputs for CENRAP 2018 Emissions Draft Technical Support Document* (May 2005). The control factors for non-EGU point sources account for Maximum Achievable Control Technology (MACT) standards and the NO_X SIP Call for industrial boilers. In addition, the newly permitted Holcim cement kiln in Ste. Genevieve County was added to the 2018 non-EGU point inventory.

The Integrated Planning Model (IPM) version 2.1.9 model output for 2018 was used for 2018 EGU point source emissions. The SMOKE IDA formatted version of the 2018 Integrated Planning Model (IPM) 2.1.9 file was prepared by Pechan for CENRAP. See the Pechan report, *Refinement of CENRAP's 2002 Emissions Inventories* (August 31, 2005), in Appendix H.3 for more information. The proprietary IPM model has been used by the EPA to simulate electrical power generation and electrical power distribution scenarios based upon "least-cost" assumptions for future years and, simultaneously, generate estimates of pollutant emissions associated with these scenarios. The IPM run was conducted by ICF under contract to the RPOs. This run corresponds with the "VISTASII_PC_1f" modeling run. This run specifically addressed the emission reductions to be realized through implementation of CAIR assuming all states participate in the EPA's trading program, Acid Rain Program (Title IV – Phases I and II), NO_X SIP Call, and state and local regulations, while incorporating unit-level updates provided by power company stakeholders.

The University of California-Riverside (UCR) ran the SMOKE model for 2018 point source emissions. The edited IPM file for EGUs was processed in SMOKE without adjustments. The growth and control factors for non-EGUs were applied using the SMOKE model. The technical support document in Appendix F describes UCR's work on the 2018 point source inventory.

7.2.2 Area Sources

The 2002 area source inventory includes emissions estimates prepared by the department's Air Pollution Control Program and CENRAP, with remaining gaps filled in with data from the NEI. Table H.9 in Appendix H.1 lists the source of the emissions estimates for each SCC in the base year area source inventory. For the categories developed by the department's Air Pollution

Control Program, the data and methods used are described in the document *Missouri Statewide Estimates for the 2002 National Emissions Inventory (NEI): Area Sources* (January 8, 2007) in Appendix H.5. The data and methods used to develop the prescribed burning, agricultural dust, and soil agricultural ammonia inventories for CENRAP can be found in the following reports prepared by Sonoma Technology in Appendix H: *Research and Development of Planned Burning Emission Inventories for the Central States Regional Air Planning Association* (July 30, 2004), *Emission Inventory Development for Mobile Sources and Agricultural Dust Sources for the Central States* (October 28, 2004), and *Research and Development of Ammonia Emission Inventories for the Central States Regional Air Planning Association* (October 30, 2003). Documentation of EPA's methods for the NEI may be found on EPA's Clearinghouse for Inventories and Emission Factors (CHIEF) website at http://www.epa.gov/ttn/chief/net/2002inventory.html.

In a contract with CENRAP, Pechan consolidated the area source data from the various sources, conducted additional quality assurance, and worked with the department's Air Pollution Control Program to make revisions where needed. In particular, corrections were made to a double-counting error of industrial surface coating VOC emissions. Pechan also converted the area source inventory to the SMOKE/IDA format. Pechan's work is described in detail in two documents included in Appendix H: *The Consolidation of Emissions Inventories* (April 28, 2005) and *Refinement of CENRAP's 2002 Emissions Inventories* (August 31, 2005).

To prepare the area inventories for modeling, UCR made several modifications to the IDA files by removing selected sources either to model them as separate source categories or to omit them from simulations completely. Fugitive and road dust sources were extracted from all stationary-area inventories and adjusted by transport factors following *Methodology to Estimate the Transportable Fraction (TF) of Fugitive Dust Emissions for Regional and Urban Scale Air Quality Analyses* (Pace 2005).

The 2018 area source emissions inventory was based on data provided by CENRAP states. Area source growth and control factors were prepared by Pechan and are documented in the following report in Appendix H.5: Development of Growth and Control Inputs for CENRAP 2018

Emissions Draft Technical Support Document (May 2005). The control factors reflect New Source Performance Standards (NSPS) for residential wood combustion and Stage II vapor recovery controls, including onboard vapor recovery.

UCR ran the SMOKE model for the 2018 area source emissions. The growth and control factors for area sources were applied within SMOKE. The technical support document in Appendix F describes UCR's work on the 2018 area source inventory. Windblown dust from non-agricultural land use categories and fire emissions were held constant from 2002 to 2018.

7.2.3 Offroad Mobile Sources

The 2002 offroad mobile source includes emissions estimates prepared by the department's Air Pollution Control Program and CENRAP, with remaining gaps filled in with EPA NEI data. Table H.10 in Appendix H.1 lists the source of the emissions estimates for each SCC in the base year offroad mobile inventory. The majority of the offroad mobile inventory was developed by Sonoma Technology under a contract with CENRAP. The methods and data used by Sonoma are described in the report *Emissions Inventory Development for Mobile Sources and Agricultural Dust Sources for the Central States* (October 28, 2004) in Appendix H.7. Information on the NONROAD model is at http://www.epa.gov/otaq/nonrdmdl.htm.

Pechan, under a contract with CENRAP, consolidated the offroad mobile source inventories from the various data sources, quality-assured the data, worked with the department's Air Pollution Control Program to make corrections where needed, and created SMOKE/IDA-formatted files. In particular, Pechan made corrections to the fuel oxygenate content used in the NONROAD model. Pechan's work is described in detail in the two documents included in Appendix H: *The Consolidation of Emissions Inventories* (April 28, 2005) and *Refinement of CENRAP's 2002 Emissions Inventories* (August 31, 2005).

The 2018 offroad mobile inventory was based on inputs from CENRAP states. Growth and control factors for locomotives, aircraft, and commercial marine vessels were prepared by Pechan. The control factors accounted for federal standards for commercial marine vessels and locomotives. For the remaining offroad mobile categories, Pechan ran the EPA's

NONROAD2004 model for 2018. EPA's NONROAD2004 model accounts for growth in equipment populations and incorporates the effects of most final federal standards, including the Tier 4 diesel engine standards and the exhaust emission standards for large spark-ignition engines, diesel marine, and land-based recreational engines. Pechan's methods are described in greater detail in the following report in Appendix H.4: Development of Growth and Control Inputs for CENRAP 2018 Emissions Draft Technical Support Document (May 2005).

UCR and applied the growth and control factors to non-NONROAD categories using the SMOKE model. In addition, UCR processed NONROAD-model categories in SMOKE without adjustments. The technical support document in Appendix F describes UCR's work on the 2018 offroad inventory

7.2.4 Onroad Mobile Sources

The department's Air Pollution Control Program and CENRAP, with contractor support, developed the 2002 and 2018 onroad mobile source emissions inventories. Sonoma Technology provided 2002 VMT data and MOBILE6 input files for all counties in the CENRAP region. MOBILE6 input files were provided only for the months of January and July for 2002. The methods and data used by Sonoma are described in the report Emissions Inventory Development for Mobile Sources and Agricultural Dust Sources for the Central States (October 28, 2004) in Appendix H.7. UCR prepared MOBILE6 input files for the remaining months of 2002 and processed the 2002 mobile emissions using the MOBILE6 model within the SMOKE framework.

Pechan prepared the VMT and MOBILE6 inputs for the 2018 onroad mobile source emissions inventory. The VMT growth factors and MOBILE6 input files were provided in SMOKE format. The MOBILE6 input files incorporated state/local control program information, including Reformulated Gasoline and the inspection and maintenance program in the St. Louis nonattainment area and low Reid vapor pressure (RVP) gasoline in the Kansas City maintenance area. For each county or group of counties modeled, two SMOKE-formatted MOBILE6 files were prepared: one representing July conditions and one representing January conditions. Pechan's methods are described in greater detail in the following report in Appendix H.4:

Development of Growth and Control Inputs for CENRAP 2018 Emissions Draft Technical Support Document (May 2005).

UCR prepared MOBILE6 input files for the remaining months of 2018 and processed the 2018 onroad mobile emissions by running the MOBILE6 model within the SMOKE framework. The SMOKE model applies the VMT growth factors. The MOBILE6 model accounts for federal motor vehicle controls, including light-duty motor vehicle engine standards and low-sulfur gasoline, and the federal heavy-duty diesel engine standards and low-sulfur diesel. The technical support document in Appendix F describes UCR's onroad mobile emissions inventory processing.

7.2.5 Biogenic Emissions

UCR generated biogenic emissions by running the BEIS3 model within the SMOKE framework. BEIS3 is a system integrated into SMOKE for deriving emissions estimates of biogenic gas-phase pollutants from land use information, emissions factors for different plant species, and hourly, gridded meteorology data. Biogenic emissions were held constant from 2002 to 2018. The technical support document in Appendix F describes the development of the biogenic emissions inventory.

7.3 PERIODIC UPDATES OF EMISSIONS INVENTORIES

Recognizing the importance of maintaining current, valid emissions information, the department's Air Pollution Control Program commits to periodically updating the Missouri statewide emissions inventories. The point source inventories will be updated on an annual basis, and the area, onroad mobile, and offroad mobile inventories will be updated every three years. The three-year updates will begin with the inventory for calendar year 2008, and follow with 2011, 2014, and so on, consistent with EPA's emissions inventory reporting requirements.

In addition to completing regular updates of Missouri's emissions inventory, the Air Pollution Control Program commits to periodically reviewing emissions information for other states and future-year emissions projections and making adjustments where needed. This effort will consist of reviewing and updating any technical data and assumptions regarding emissions growth rates,

implementation of emissions controls, and geographic distribution of emissions. The periodic reviews will be coordinated with other states and consultation partners and will be conducted in conjunction with the five-year progress reports discussed in section 2.6.

8.0 MODELING ASSESSMENT

8.1 MODELING REQUIREMENTS

40 CFR 51, Appendix W provides modeling guidelines for conducting regional-scale modeling for particulate matter and visibility. The EPA recommends the use of one of the three following models to simulate pollutants impairing visibility: Community Multiscale Air Quality (CMAQ), Comprehensive Air quality Model with extensions (CAMx), and Regional Modeling System for Aerosols and Deposition (REMSAD). CENRAP contractors performed regional modeling using CMAQ and CAMx.

The CMAQ Model is an Eulerian model that simulates the atmospheric and surface processes affecting the transport, transformation and deposition of air pollutants and their precursors. An Eulerian model computes the numerical solution of partial differential equations of plumes on a fixed grid, while other models may lose accuracy or need regridding as the plumes expand.

CAMx is a computer modeling system for the integrated assessment of photochemical and particulate air pollution. CAMx incorporates all of the technical attributes demanded of state-of-the-art photochemical grid models, including two-way grid nesting, a subgrid-scale Plume-in-Grid module to treat the early dispersion and chemistry of point source NO_X plumes, and a fast chemistry solver.

In the July 1, 1999 publication of the Regional Haze Rule in the Federal Register, EPA defined the uses of regional modeling as follows:

- Analyses and determination of the extent of emissions reductions needed from individual states
- Analyses and determination of emissions needed to meet the progress goal for the Class I area
- Analyses to support conclusion that the Long-Term Strategy provides for reasonable progress
- Analyses to calculate the resulting degree of visibility improvement that would be achieved at each Class I area

- Analyses to compare visibility improvement between proposed control strategies

8.2 MODEL INPUTS

8.2.1 Selection of Episodes

The calendar year 2002 was selected for the base year for CENRAP regional haze annual modeling consistent with EPA guidance. The Technical Support Document provides additional information on the selection of 2002 as the base year for regional haze modeling and is found at Appendix F.

8.2.2 Selection of Modeling Domain

CENRAP conducted emissions and air quality modeling on the 36 km national RPO domain. This domain consists of a 148 by 112 array of 36 km by 36 km grid cells and covers the continental United States. The Technical Support Document provides additional information on the modeling domain and is found at Appendix F.

8.2.3 Emission Inventories

The emissions inventory includes VOC, NO_X, CO, SO_2, PM_{10}, $PM_{2.5}$, and NH_3 emissions from all anthropogenic and biogenic sources. The emissions inventory information submitted by state, tribal, and local agencies to the 2002 NEI formed the basis of the 2002 CENRAP emissions inventory. The NEI data was supplemented with non-point source emissions inventories developed for CENRAP by Sonoma Technology. These CENRAP-specific inventories addressed agricultural and prescribed burning, onroad and offroad mobile sources, agricultural tilling and livestock dust, and agricultural ammonia. In addition, Pechan assisted CENRAP by quality-assuring the emissions inventory and preparing day- and hour-specific emissions for EGUs based on Continuous Emissions Monitor (CEM) data for the model performance evaluation.

Emissions inputs for the air quality model were prepared using the SMOKE emissions modeling system. The CENRAP modeling emissions inventory consists of several distinct datasets: the 2002 base case for model performance evaluation, 2002 typical, 2018 base case, and the 2018 control strategy scenario. Its spatial extent is the RPO 36 km modeling domain, which covers

the continental U.S. plus portions of Canada and Mexico. The inventory was refined through several rounds of CENRAP workgroup review and revision, beginning with the initial Base A version and culminating in the Base G inventory. The Technical Support Document provides the methodologies for the SMOKE emissions processing and is found at Appendix F. A summary of the development of the emissions inventory can be found in Chapter 7.

8.2.4 Meteorology

The Fifth-Generation NCAR / Penn State Mesoscale Model (MM5) is the latest in a series that developed from a mesoscale model used by Anthes at Penn State in the early 70's that was later documented by Anthes and Warner (1978). Since that time, it has undergone many changes designed to broaden its usage. These include (i) a multiple-nest capability, (ii) nonhydrostatic dynamics, which allows the model to be used at a few-kilometer scale, (iii) multitasking capability on shared- and distributed-memory machines, (iv) a four-dimensional data-assimilation capability, and (v) more physics options. The model (known as MM5) is supported by several auxiliary programs, which are referred to collectively as the MM5 modeling system. Since MM5 is a regional model, it requires an initial condition as well as a lateral boundary condition to run. To produce a lateral boundary condition for a model run, one needs gridded data to cover the entire time period that the model is integrated. The Technical Support Document provides the methodologies for this process and is found at Appendix F.

8.3 MODEL PERFORMANCE EVALUATION

Model evaluations compared concentrations of various pollutants simulated by CMAQ and CAMx with observations from:

- IMPROVE
- Clean Air Status and Trends Network (CASTNet)
- Speciated Trends Network (STN)
- Aerometric Information Retrieval Systems (AIRS)
- South Eastern Aerosol Research and Characterization (SEARCH)

The CMAQ and CAMx models were evaluated against ambient measurements of PM species, gas-phase species and wet deposition. Numerous iterations of CMAQ and CAMx 2002 base

case simulations and model performance evaluations were conducted during the course of the CENRAP modeling study, most of which have been posted on the CENRAP modeling website (http://pah.cert.ucr.edu/aqm/cenrap/cmaq.shtml) and presented in previous reports and presentations for CENRAP. In general, the model performance of the CMAQ and CAMx models for SO_4 and elemental carbon (EC) was good. Model performance for nitrate (NO_3) was variable, with a summer underestimation and winter overestimation bias. Performance for OMC was also variable, with the inclusion of the Secondary Organic Aerosol Modules enhancement in CMAQ Version 4.5 greatly improving the CMAQ summer OMC model performance. Model performance for Soil and coarse mass was generally poor. Part of the poor performance for soil and coarse mass is believed to be due to measurement-model incommensurability whereby the IMPROVE measured values are due in part to local fugitive dust sources that are not captured in the model's emission inputs and 36 km grid resolution. Detailed information on the model performance evaluations is found in the Technical Support Document in Appendix F.

8.4 BASE G MODEL SIMULATIONS

8.4.1 2018 Base G visibility projections

The 2018 Base G modeling run reflects emissions growth and "on the books" controls, which are state and federal controls that will be implemented between the 2002 base year and the 2018 future year. The 2018 emissions for EGUs were based on simulations of the IPM that took into account the effects of the CAIR trading program. In addition, reductions anticipated from BART controls for EGUs in Oklahoma, Arkansas, Kansas, and Nebraska were included. Emissions for onroad and offroad mobile sources were based on activity growth and emissions factors from the EPA MOBILE6 and NONROAD models, respectively, which reflected emissions reductions from the Tier 2 and Tier 4 mobile source rules. Area sources and non-EGU point sources were grown to 2018 levels.

The two important regional haze metrics are the average visibility for the worst 20 percent and best 20 percent days from the 2000-2004 five-year baseline period. The results from the 2002 and 2018 CMAQ and CAMx simulations were used in a relative sense to scale observed PM concentrations from the 2000-2004 baseline to 2018 levels from which 2018 visibility estimates were obtained. The CENRAP 2018 visibility conditions were calculated following EPA default

visibility projection procedures and are labeled “Method 1 Prediction” in Figures 8.1 and 8.2. The steps involved in the visibility calculations are described below:

1. For each Class I area and each monitored day, daily visibility based on IMPROVE data and the new IMPROVE equation was ranked for the five-year baseline period (2000-2004) to identify the worst 20 percent and best 20 percent visibility days for each year in the baseline period.
2. The CMAQ air quality model was used to simulate the base year (for CENRAP the 2002 annual period was simulated) and a future-year (2018). The resulting information was used to develop Class I area-specific relative reduction factors (RRFs) for each of the six components of light extinction in the IMPROVE equation (SO_4, NO_3, EC, OMC, Soil and CM).
3. The RRFs were multiplied by the measured 24-hour PM concentration for each day from the worst and best 20 percent days in each year from the five-year baseline period to obtain projected future-year 24-hour PM concentrations for the worst and best 20 percent days.
4. The future-year (2018) daily extinction was computed using the new IMPROVE equation and the projected PM concentrations for each of the worst and best 20 percent days in the five-year baseline from step 3.
5. For each of the worst and best 20 percent days within each year of the five-year baseline, the future-year daily extinction was converted to deciview. The daily deciview values were averaged within each of the five years separately to obtain five years (or as many years with valid data in the 2000-2004 baseline) of average deciview visibility for the worst and best 20 percent days.
6. The five years of deciview visibility were averaged to obtain the 2018 estimated visibility.

The 2018 visibility projections for the worst 20 percent days and best 20 percent days are compared against a 2018 point on the Uniform Rate of Progress (URP) glidepath or the “2018 URP point.” The 2018 URP point is obtained by constructing a linear visibility glidepath in deciviews from the observed 2000-2004 Baseline for the worst 20 percent days to the 2064

Natural Conditions. The 2018 URP point is where the linear glidepath crosses the year 2018. Figures 8.1 and 8.2 present the 2018 visibility projections for Hercules Glades and Mingo. As seen in these figures, the 2018 visibility projections at both the Hercules Glades and Mingo Class I areas meet the 2018 point on the URP glidepath for the worst visibility days and exhibit no degradation on the best visibility days. For the worst 20 percent days, the 2018 projection for Hercules Glades is 23.06 dv, compared to the URP point of 23.14 dv. The 2018 projection for Mingo is 23.71 dv, as compared to the URP point of 24.37 dv.

Additional information on the CENRAP visibility projections based on the Base G modeling results is summarized in 4.4. of the Technical Support Document (TSD), which indicates that Appendix D of the TSD provides details for each Class I area in the CENRAP region using the new IMPROVE equation.

8.4.2 Other RPO's visibility projections

The 2018 visibility projections for the two Missouri Class I areas are also available from the VISTAS and MRPO modeling. At Hercules Glades, the three RPOs' 2018 visibility projections are in close agreement with each other, estimated to achieve 102 percent, 101 percent and 96 percent of the 2018 URP point. The CENRAP and VISTAS 2018 visibility projections are also very close at Mingo, 118 percent and 114 percent, respectively. However, the MRPO 2018 visibility projections are approximately 15 percentage points lower than the CENRAP and VISTAS projections at Mingo. The reasons why the MRPO 2018 visibility projections are less optimistic than CENRAP and VISTAS are unclear. The discrepancy could be due to the use of different emissions inventories. CENRAP's Base G inventory included IPM 2.1.9 results for 2018 EGU emissions that had been quality-assured and edited by CENRAP and VISTAS states and stakeholders, while MRPO's latest modeling inventory used IPM 3.0 results that did not include edits from VISTAS or most of the CENRAP states. The department's Air Pollution Control Program concluded that CENRAP projections for Mingo and Hercules Glades should be more accurate due to a better emissions inventory for our states. Additional analysis including the IPM 3.0 results with states' review will be considered during the five-year review period.

9.0 BEST AVAILABLE RETROFIT TECHNOLOGY (BART)

9.1 BART REQUIREMENTS

The EPA's 1999 Regional Haze Rule singles out certain older emission sources that have not been regulated under other provisions of the Clean Air Act for additional controls. Older sources that contribute to visibility impairment in Class I areas are required to implement BART or an emissions trading or other alternative program that will achieve greater reasonable progress than would be achieved through the installation and operation of BART. On July 6, 2005, EPA published a revised final rule, including Appendix Y to 40 CFR 51 "Guidelines for BART Determinations Under the Regional Haze Rule" that provides direction to states on determining which of these older sources may need to install BART and how to determine BART.

Based on comments received from EPA Region VII, sources originally not included in the BART air quality review were re-examined. Some additional sources were found to be BART eligible and were evaluated in the same fashion as the original sources. Upon completion of the BART air quality screen and draft refined modeling analyses; the State of Missouri has found one source that is subject to BART. This source (Holcim – Clarksville) has signed a consent agreement with emission limits that represent BART for the applicable source. This agreement with the department is included in this submittal as the enforceable mechanism for the necessary emission control requirements. No other sources were found to be subject to BART and, therefore, implementation of an emissions trading program, other emission controls or other alternative measure in place of BART are not necessary.

9.2 BART – ELIGIBLE SOURCES IN STATE OF MISSOURI

The facilities with BART-eligible units in the State of Missouri are shown in Table 9.1 (including the newly identified sources). A detailed description of each BART-eligible emission unit is included in Appendix I.

Table 9.1: Facilities with BART-eligible Units in the State of Missouri

*BART-eligible EGU units included in the CAIR assumed to be BART for SO_2 and NO_X
** Other supporting units listed in facility summary later in this section
Italics means BART-eligible source identified after EPA comments

The BART-eligible sources were identified using the methodology in the Guidelines for BART Determinations under the Regional Haze Rules or "Guidelines" (40 CFR 51, Appendix Y). For an emission unit source to be identified as BART-eligible, the State of Missouri used these criteria from the Guidelines:

- One or more emissions units at the facility fit within one of the 26 categories listed in the Guidelines;
- The emission unit(s) were in existence on August 7, 1977 and began operation at some point on or after August 7, 1962; and
- The limited potential emissions from all emission units identified in the previous two bullets emission units were greater than 250 tons or more per year of any of these visibility-impairing pollutants: SO_2, NO_X, and PM_{10}.

The Guidelines recommend addressing these visibility-impairing pollutants: SO_2, NO_X, and particulate matter. The State of Missouri addressed these three pollutants and used particulate matter less than 10 microns in diameter (PM_{10}) as an indicator for particulate matter to identify BART-eligible units, as the Guidelines suggest. Consistent with the Guidelines, the State of Missouri did not evaluate emissions of VOCs and ammonia in BART determinations for these reasons:

1) the majority of VOC emissions in Missouri are biogenic in nature and specifically the areas near Mingo and Hercules Glades are very rich in biogenic emissions (limited ability to reduce organic concentrations at the Class I areas),
2) the largest areas of anthropogenic VOC emissions in Missouri exist in the metropolitan areas (St. Louis and Kansas City) where VOC emission control has been undertaken to address ozone attainment issues (meaning large VOC sources have already been controlled),
3) the other category that would have substantial, uncontrolled VOC emissions is charcoal kilns, the department required existing charcoal kilns to install afterburners or shutdown noncompliant kilns as a result of 10 CSR 10-6.330,
4) the overall ammonia inventory is very uncertain and the amount of anthropogenic emissions at the sources that were BART-eligible was relatively small, and

5) No additional sources were identified that had greater than 250 tons per year ammonia and required a subsequent BART analysis.

The State of Missouri identified potentially BART-eligible source by reviewing the emission inventory database and extracting data for facilities within the 26 categories identified. A survey was conducted for the facilities within this group asking for large source identification and the timing of the installation and operation of those sources. The sources listed in Table 9.1 have been identified as sources that meet the criteria for inclusion as BART-eligible sources. Beyond the three primary visibility-impairing pollutants (SO_2, NO_X, and PM_{10}), the sources were also asked to identify ammonia and VOC emissions. The survey and resultant tabular response information are contained in Appendix J and Appendix I, respectively.

9.3 DETERMINATION OF SOURCES SUBJECT TO BART

Upon completion of the survey, the BART-eligible sources were divided into four distinct groups: (1) electric generating units participating in the CAIR trading program, (2) sources that have final new source review (construction) permits requiring a BART-eligible unit "shutdown" or no current operating permit at the facility, (3) sources that have gone through a subsequent construction permitting exercise for units that would have been BART-eligible based on original installation date, and (4) all other units that underwent a screen-modeling evaluation to determine the visibility impact on the applicable Class I area(s).

The first and fourth groups were evaluated initially using a screen-modeling technique for visibility impact. The first group (CAIR EGUs) was modeled collectively using all BART-eligible sources for only the PM impacts on the applicable Class I areas (NOTE: After EPA comment, two additional CAIR EGU facilities were discovered to be BART-eligible and additional analysis was performed). All the sources in the fourth group were modeled independently. The second group included some or all of the BART-eligible sources at four installations. River Cement, Doe Run – Glover, Continental Cement, and Mississippi Lime all had units that were part of a voluntary shutdown or being removed due a specific construction permit condition. To be clear, the Doe Run – Glover facility does not have a current operating permit for any of the BART-eligible units at the facility. The department sent a notice to the

company on November 13, 2007, that detailed the termination of the operating permit for the BART-eligible units after a thirty-day period allowed for the company to provide additional information. This period expired on December 13, 2007, and the permit was closed out. Therefore, the pyro-process units at Glover can not restart without a new construction permit requiring Best Available Control Technology (BACT) evaluation for each. These BART-eligible units were not included in the modeling analyses and are shown in Table 9.2. During the public comment period, Mississippi Lime Company provided a comment that changed the units that were subject to the BART air quality screening evaluation. Mississippi Lime Company has provided a permit modification that includes the continued use of Peerless Rotary Kiln #4 (EP69) at the facility. The unit was originally subject to shutdown provisions in the applicable permit, but the updated information required a new evaluation of the facilities' BART-eligible units. The other unit in the shutdown provision (PRK #3 – EP68) has been dismantled.

Table 9.2: Units Removed from BART Consideration Due to Shutdown or Federal Permit Requiring Shutdown

Facility/Facility ID	Units	Reason for Removal from BART Consideration
Doe Run – Glover / 29-083-0008	Pyro-process units	No operating permit
RC Cement / 29-099-0002	4-K-02	Permit #122005-005
Mississippi Lime / 29-186-0001	EP68	Permit #122002-007
Continental Cement / 29-173-0001	KP01	Permit #072007-008

The third category illustrates a source that has undergone a major source permitting exercise for the units that would have been BART-eligible based on installation date. Doe Run – Buick underwent a Prevention of Significant Deterioration (PSD) review for Permit #0989-003 and a subsequent review for Permit #012005-008. Each review found that the blast furnace units had installed Best Available Control Technology (BACT).

The BART-eligible unit at Doe Run – Buick is the blast furnace (referenced as EP-08, Main Stack). Under the 2005 construction permit, the entire facility is limited to 3,400 tons per year of SO_2 with vast majority coming from the blast furnace. The other emissions from this unit are very limited - NOx and PM emissions are less than 10 tons per year. Therefore, a BART evaluation of the source could be required for SO_2 if impact predicted from visibility modeling

exceeded the 0.5 deciview threshold at the nearby Mingo National Wildlife Refuge. However, the department did not conduct this visibility evaluation initially due to a 2005 Best Available Control Technology (BACT) review for blast furnace SO_2 control. The department assumed that since a BACT finding was made for this unit in the recent past that a BART evaluation was unnecessary. However, EPA Region VII commented that this was not sufficient for a BART finding.

Therefore, department staff reviewed the SO_2 BACT finding for the blast furnace and found that three different technologies were considered: wet scrubbing, dry scrubbing, and de-sulfurization of feed materials. Dry scrubbing was eliminated as technically infeasible due to excess hazardous waste generation. Wet scrubbing of the exhaust gas in a packed tower scrubber was selected as the best available technical option for significant control. However, the capital cost of this type of unit was estimated to be $24,100,000 with an annualized system cost of $11,000,000. The cost per ton SO_2 reduced was $3,537, which demonstrated that this alternative was cost-ineffective. The continued use of chemical de-sulfurization of the battery paste input to the smelting process at the Buick facility was determined to be BACT and resulted in the SO_2 emission limit in the 2005 permit. The BART finding is equivalent to the BACT finding in this case due to the high cost of the wet scrubbing technology and the on-going benefit of the de-sulfurization process. In addition to this cost finding and to better understand the visibility impact of the BART-eligible unit, the department conducted a sensitivity analysis of the Doe Run Buick facility on the nearby Mingo Class I area. The results of this sensitivity are included below in the refined screening discussion under Section 9.3.7 – Doe Run Buick.

Under the Guidelines, the State has these options regarding its BART-eligible sources: a) make BART determinations for all sources or b) consider exempting some sources from BART because they do not cause or contribute to visibility impairment in a Class I area. The State of

Missouri has chosen option b. If a state chooses option b, then the Guidelines suggest three sub-options for determining that certain sources need not be subject to BART:

(1) Individual source attribution approach (dispersion modeling).

(2) Use of model plants to exempt sources with common characteristics.

(3) Cumulative modeling to show that no sources in a state are subject to BART.

The State of Missouri has chosen sub-options 1 and 3 above to notify sources that would be required to conduct refined analyses based on the results of the screening analyses discussed previously. The goal was to determine if these sources cause or contribute to visibility impairment using the CALPUFF model. As discussed previously, the CAIR-affected electric generating units were collectively modeled for PM emissions only due to the presumptive BART determination for NO_X and SO_2 emissions from these sources. The results of this evaluation are included in Table 9.3. Examples of CALPUFF/CALPOST modeling input files used for determining which facilities are subject to BART are included in Appendix K. The CALPOST files included are not universal for all the facilities modeled. The Noranda facility utilized speciation of the PM emissions to include both a coarse fraction and a fine fraction. In addition, the remaining facilities included the PM_{10} emissions component as fine particulate matter (PMF) in the CALPOST analyses, but were sometimes called PM_{10} or PMF depending on the individual screening analysis.

The State of Missouri utilized two different methods for evaluation of visibility impacts: (1) Method 2 – modeled relative humidity factors are calculated for each hour/day of the modeling period and (2) Method 6 – an average relative humidity factor is applied for each Class 1 area being evaluated. Based on the analyses, it was determined that Method 2 provides more conservative results for visibility calculation. Since only Method 6 was required by the BART rulemaking, the use of Method 2 gives added confidence to the findings regarding sources that did not trigger refined modeling. Some or all of the following Class 1 areas were evaluated based on source location: Mingo, Hercules Glades, Upper Buffalo, and Mammoth Cave (Kentucky). The screening evaluation criterion was a maximum deciview impact of greater than 0.5 deciview to require a refined analysis. Six sources were identified during the source-specific screening analyses and these sources were notified to provide refined CALPUFF modeling

analyses and/or the department conducted the refined screening analyses. In accordance with the guidelines, a contribution threshold of 0.5 deciview (98th percentile) was used for determining which sources were subject to BART using the refined modeling approach.

The results of the individual screening analyses for each source are included in Table 9.3.

BOLD denotes deciview impact over the 0.5 threshold
Italics denotes sources that were included as a result of a public comment
* University of Missouri – Columbia

The additional analysis on the two CAIR EGU facilities (Associated Electric – Thomas Hill and Aquila – Lake Road) mentioned above did not illustrate any discernable visibility difference (all CALPOST values are less than or equal to 0.001). Therefore, results were not presented in Table 9.3. Emissions from BART-eligible units at BASF Corporation were not included in the screening analysis, but were included in the refined screening analysis detailed below.

In addition to the maximum impact metric shown above in the screening analyses, the State of Missouri evaluated the number of days with visibility impacts over the contribute (0.5 deciview) and cause (1.0 deciview) thresholds to decide which Class I area would be necessary for refined analyses. The results shown in Table 9.4 illustrate the number of days over the threshold for each source/Class I area combination. Again, these results were utilized to identify which Class I areas were more likely to be impacted and would need further refined analyses.

Table 9.4: Number of Days over the 0.5 Deciview Threshold

Facility	Class I Area	Method 2 Days	Method 6 Days	Year
Noranda	Hercules Glades	1	0	2001
Noranda	Hercules Glades	4	1	2002
Noranda	Hercules Glades	1	1	2003

Based on the screening analyses, the State of Missouri required Noranda to submit refined modeling for Mingo, and the University of Missouri-Columbia (UMC) to submit refined analysis for Mingo, Hercules Glades, and Upper Buffalo. The fundamental difference between both sets of refined analyses and the previous screening evaluation was the use of meteorological observations in the development of the CALMET files used in the CALPUFF evaluations. The emission rates were consistent between the screening analyses and the refined analyses, as were the meteorological years for the evaluation (2001-2003). In order to develop the new refined meteorological dataset, both companies chose different grid parameters for the evaluation. The grid structure is contained in Table 9.5 for both analyses. It should be noted that the UMC CALMET analyses were utilized for all the other refined modeling conducted by the department based on the revision to the BART-eligible source list detailed above. This means that the same meteorological dataset was utilized for refined modeling of: BASF Corporation, Independence Power and Light – Blue Valley, Columbia Municipal Power Plant, Marshall Municipal, and

Holcim - Clarksville. Each of these BART-eligible sources were evaluated for Mingo, Hercules Glade, and Upper Buffalo Class I areas.

Table 9.5: Grid Structure for Refined Terrain, Land Use, and CALMET Analyses

Variable	RLAT0	RLON0	RLAT1	RLAT2	XREFKM	YREFKM	NX	NY	DGRIDKM
Noranda	36.0874	90.8491	36	40	0	0	83	80	2.0
UMC	37	92	30	45	-258	-330	87	111	6.0

The choices of the domain are appropriate for these evaluations of the relevant Class I areas. Please note that based on previous guidance from the FLMs on new source review evaluations, the domain for each analysis extends at least 50 km beyond the source(s) and Class I area(s) in each direction. The very fine grid spacing for Noranda is due to the proximity of the source to the Mingo National Wildlife Refuge (~60 km). The list of terrain and land use files used in the analyses for each project is included in Appendix L.

In addition to the grid structure change, meteorological observations were also utilized to refine the MM5 data used in the screening analyses. The lists of specific stations used along with relevant locational information for each station and upper air, surface, and precipitation data are included in Appendix L.

Based on the review process and discussions with the facilities during the screening analysis, the source parameter, emissions, and many other CALPUFF/CALPOST issues were addressed to allow for the use of the screening files as a basis for the development of the refined analysis. Nonetheless, the issues noted are presented below for clarification purposes.

9.3.1 University of Missouri-Columbia

The review for the BART-eligible unit at UMC (Boiler 10) included the verification of the CALPUFF concentration results along with a slightly different methodology for calculation of the visibility impacts at the relevant Class I areas. The methodology utilized by the contractor in this case included the use of speciation for the PM_{10} emissions from the boiler and the POSTUTIL program for the CALPUFF results. The speciation profile was obtained from the National Park Service web site at www2.nature.nps.gov/air/Permits/ect/ectCoalFiredBoiler.cfm from the Pulverized Coal – Dry Bottom Boiler with fabric filter (baghouse) control spreadsheet.

The department used the PM_{10} emission rate from the boiler and converted the concentrations directly to PMF for calculation of the visibility change at the relevant Class I areas. Each set of results is presented below in Table 9.6, 9.7, and 9.8.

Table 9.6: UMC Refined Analysis Results (Boiler PM Speciation Profile)

Facility	Class I Area	Maximum Method 6 Impact	8^{th} Highest (98%) M6 Impact	Days over 0.5 Deciview Threshold	Year
UMC	Mingo	0.291	0.144	0	2001
UMC	Mingo	1.389	0.188	2	2002
UMC	Mingo	0.582	0.323	2	2003
UMC	Hercules Glades	0.709	0.310	2	2001
UMC	Hercules Glades	0.542	0.195	1	2002
UMC	Hercules Glades	0.591	0.271	2	2003
UMC	Upper Buffalo	0.466	0.232	0	2001
UMC	Upper Buffalo	0.714	0.210	1	2002
UMC	Upper Buffalo	0.406	0.226	0	2003

Table 9.7: UMC Refined Analysis Results (PM_{10}=PMF) Method 2

Facility	Class I Area	Maximum Method 2 Impact	8^{th} Highest (98%) M2 Impact	Days over 0.5 Deciview Threshold	Year
UMC	Mingo	0.304	0.193	0	2001
UMC	Mingo	2.757	0.236	2	2002
UMC	Mingo	0.641	0.376	2	2003
UMC	Hercules Glades	0.804	0.377	3	2001
UMC	Hercules Glades	0.524	0.228	1	2002
UMC	Hercules Glades	0.647	0.413	5	2003
UMC	Upper Buffalo	0.855	0.248	2	2001
UMC	Upper Buffalo	0.941	0.227	3	2002
UMC	Upper Buffalo	0.549	0.339	1	2003

Table 9.8: UMC Refined Analysis Results (PM_{10}=PMF) Method 6

Facility	Class I Area	Maximum Method 6 Impact	8^{th} Highest (98%) M6 Impact	Days over 0.5 Deciview Threshold	Year
UMC	Mingo	0.290	0.144	0	2001
UMC	Mingo	1.389	0.188	2	2002
UMC	Mingo	0.581	0.323	2	2003
UMC	Hercules Glades	0.708	0.310	2	2001
UMC	Hercules Glades	0.542	0.195	1	2002
UMC	Hercules Glades	0.591	0.270	2	2003
UMC	Upper Buffalo	0.465	0.232	0	2001
UMC	Upper Buffalo	0.714	0.210	1	2002
UMC	Upper Buffalo	0.405	0.226	0	2003

The results clearly demonstrate that Boiler 10 at the University of Missouri – Columbia does not exceed the 98th percentile visibility impact threshold of 0.5 deciview for CALPOST Method 2 methodology, which is more conservative than the required Method 6 methodology. When comparing Table 9.6 and 9.8, it is apparent that the use of the PM_{10} speciation profile by the source did not impact the visibility change. This is due to the fact that SO_2 emissions from this boiler contribute over 90 percent of the visibility impact at all the relevant Class I areas evaluated when the impacts are above 0.5 deciview. Further, the SO_2 emissions calculation from this source was based on a potential maximum emission rate (maximum hourly design rate * emission factor).

9.3.2 Noranda

The Noranda evaluation is one of the BART analysis conducted by the State of Missouri with emission rates that do not represent the maximum allowable rates for all pollutants. In fact, most of the sources from Noranda are represented by the maximum allowable rates. However, there are five sources that had maximum 24-hour actual SO_2 emissions calculated: (1) EP-59, Monitor – Potline 1; (2) EP-60, Monitor – Potline 2; (3) EP-61, Stack – Potline 1&2; (4) EP-98, Carbon Bake Furnace 1; and (5) EP-99, Carbon Bake Furnace 2. For the first three sources, the methodology for calculating the emissions was as follows:

1) Obtain the maximum combined daily aluminum tapped for Lines 1 & 2 from 2000-2005 with the knowledge that tapped aluminum does not necessarily reflect production in the plant due to day-to-day carryover of aluminum in certain situations,
2) Obtain the maximum coke sulfur content,
3) Calculate the maximum ratio of tons anode consumed to tons aluminum, and
4) Multiply the maximum daily tapped aluminum (December 24, 2004) by the maximum ratio of tons anode/tons aluminum (0.413), the maximum coke sulfur content (2.82 percent), and the molecular weight ratio of SO_2 to S in the process (1.998).

The resultant calculation follows:

Line 1 468,725 tons aluminum/day * 0.413 * 0.0282 * 1.998 = 10,907.2 lb SO_2/day

Line 2 600,400 tons aluminum/day * 0.413 * 0.0282 * 1.998 = 13,971.3 lb SO_2/day

These emissions were then distributed to the stack and roof monitors using a previous permit relationship (95 percent stack vs. 5 percent monitor) for each line. The final modeled emission rate for these three sources was:

Monitor – Potline 1 => 10,907.2 lb SO_2/day * 0.05 = 545.4 lb SO_2/day
Monitor – Potline 2 => 13,971.3 lb SO_2/day * 0.05 = 698.6 lb SO_2/day
Stack for Potline 1&2 => 24,878.5 lb SO_2/day * 0.95 = 23,634.5 lb SO_2/day

It should be noted that the NO_X emission rates for these sources also used the same maximum tapping rates for this calculation.

The carbon bake furnace emissions were calculated using the monthly amount of pitch received along with the maximum sulfur content of the pitch in any month during the 5-year period. This information was evaluated for January 2000 – December 2005. The maximum product of the amount and the pitch S content was September 2005 (2,230 tons pitch received). The maximum sulfur content in the pitch was observed in November 2005 (0.72 percent S). The calculation of emissions from all three furnaces is as follows:

2,230 tons pitch/month * (0.0072 ton S/ ton pitch) * 1.998 ton SO_2/ton S =
31.634 ton SO_2/month

Then, the aluminum production at the three potline/furnace combinations for September 2005 was documented and a production ratio was calculated for each set. This ratio was then multiplied for potlines 1 and 2 by the total maximum SO_2 emissions/month. The daily "maximum" was evaluated using the maximum monthly emissions divided by 30 days/month. The calculation of emissions is as follows:

14,068,215 September 2005 production Line 1
13,844,190 Production Line 2

15,045,080 Production Line 3

Percent Line 1 Production = 32.75%

Percent Line 2 Production = 32.23%

Percent Line 3 Production = 35.02%

Line 1 Emissions = 31.634 ton SO_2/month * 0.3275 / 30 day/month =
0.3453 ton SO_2/day = 690.68 lb SO_2/day

Line 2 Emissions = 31.634 ton SO_2/month * 0.3223 / 30 day/month =
0.3399 ton SO_2/day = 679.71 lb SO_2/day

All these emissions were utilized in both the screening and the refined meteorological evaluations for Noranda's impacts and can be found in Appendix M.

One issue was identified with respect to the refined analyses completed by Noranda's contractor. In CALMET, the location of the surface, upper air, and precipitation stations is required to allow the model to develop the appropriate 3-D meteorological fields for input into CALPUFF. During the review, it was discovered that the location of the precipitation stations utilized in the Noranda project were based on incorrect latitude and longitude data procured from another source. Therefore, at this time, the results presented in Tables 9.9 and 9.10 reflect the previous Noranda submittal and the corrected submittal. As can be seen by direct comparison of the results, both sets are nearly identical and reflect that Noranda's BART-eligible sources do not cause or contribute to a visibility problem at Mingo.

Table 9.9: Noranda Refined Analysis Results (Original Submittal)

Facility	Class I Area	Max M2 Impact	98% M2 Impact	Days > 0.5 (M2)	Max M6 Impact	98% M6 Impact	Days >0.5 (M6)	Year
Noranda	Mingo	0.770	0.340	3	0.654	0.373	2	2001
Noranda	Mingo	0.812	0.427	3	0.653	0.416	3	2002
Noranda	Mingo	0.804	0.444	5	0.745	0.406	4	2003

Table 9.10: Noranda Refined Analysis Results (Revised CALMET)

Facility	Class I Area	Max M2 Impact	98% M2 Impact	Days > 0.5 (M2)	Max M6 Impact	98% M6 Impact	Days >0.5 (M6)	Year
Noranda	Mingo	0.769	0.340	2	0.660	0.373	2	2001
Noranda	Mingo	0.775	0.412	3	0.653	0.416	3	2002
Noranda	Mingo	0.799	0.447	5	0.745	0.435	4	2003

The results clearly demonstrate that the sources at Noranda do not exceed the 98th percentile visibility impact threshold of 0.5 deciview even if the more conservative CALPOST Method 2 methodology is used.

9.3.3 Independence Power and Light – Blue Valley

The emission rates used for the BART-eligible unit (Boiler #3) at Independence Power and Light were generated by using the maximum boiler heat input (540 MMBTU/hr) and the minimum heat content for the coal used over the last five years (10,100 BTU/lb in 2004). This produced a maximum hourly design rate of 26.73 tons coal / hour. This design rate was multiplied by the highest annual emission factor for the last five years for each pollutant of interest: SO_2 – 115.14 lb SO_2/ton coal, 9.70 lb NO_X /ton coal, and 35.88 lb PM_{10}/ton coal (pre-control). For PM_{10}, the uncontrolled emissions were multiplied by (1-Control Efficiency%/100) to reflect the operation of an electrostatic precipitator. The resultant emissions were:

SO_2 -- 26.73 tons coal/hour * 115.14 lb SO_2/ ton coal * 24 hours/day = <u>73,684.6 lb SO_2/day</u>
NO_X – 26.73 tons coal/hour * 9.7 lb NO_X /ton coal * 24 hours/day = <u>6,222.7 lb NO_X /day</u>
PM_{10} – 26.73 tons coal/hour * 35.88 lb PM_{10}/ton coal * (1-95.5/100) * 24 hours/day =
<u>1035.80 lb PM_{10}/day</u>

As previously mentioned, the refined meteorological dataset for this analysis was originated by the University of Missouri – Columbia. The results of the refined analysis for Mingo, Hercules, and Upper Buffalo are presented in Table 9.11 including the 8th highest (98 percentile) values. Also, as with the department's analysis of the University of Missouri – Columbia's boiler, the same PM_{10} direct conversion to PMF calculation methodology was utilized to determine visibility impacts in CALPOST.

Table 9.11: Independence Power and Light Refined Analysis Results

Facility	Class I Area	Max M2 Impact	98% M2 Impact	Days > 0.5 (M2)	Max M6 Impact	98% M6 Impact	Days >0.5 (M6)	Year
Ind. P&L	Mingo	0.724	0.288	2	0.513	0.226	1	2001
Ind. P&L	Mingo	1.990	0.346	6	1.415	0.289	3	2002
Ind. P&L	Mingo	0.912	0.295	3	0.487	0.233	0	2003
Ind. P&L	Hercules	1.726	0.328	3	0.890	0.327	2	2001
Ind. P&L	Hercules	1.031	0.283	3	0.506	0.301	1	2002
Ind. P&L	Hercules	0.939	0.345	3	0.501	0.217	1	2003
Ind. P&L	Upper Buffalo	1.097	0.333	5	0.737	0.286	2	2001
Ind. P&L	Upper Buffalo	0.465	0.292	0	0.449	0.277	0	2002
Ind. P&L	Upper Buffalo	0.453	0.263	0	0.455	0.299	0	2003

The results demonstrate that the source at Independence Power and Light does not exceed the 98th percentile visibility impact threshold of 0.5 deciview even if the more conservative CALPOST Method 2 methodology is used.

9.3.4 Marshall Municipal Utilities

The emission rates used for the BART-eligible unit (Coal-fired Boiler – EP05) at Marshall were generated by using the maximum boiler heat input (235 MMBTU/hr) and the minimum heat content for the coal used over the last five years (10,653 BTU/lb in 2005). This produced a maximum hourly design rate of 11.03 tons coal / hour. This design rate was multiplied by the highest annual emission factor for the last five years for each pollutant of interest: SO_2 – 134.90 lb SO_2/ton coal, 22 lb NO_X/ton coal, and 19.92 lb PM_{10}/ton coal (pre-control). For PM_{10}, the uncontrolled emissions were multiplied by (1-Control Efficiency%/100) to reflect the operation of an electrostatic precipitator. The resultant emissions were:

SO_2 -- 11.03 tons coal/hour * 134.90 lb SO_2/ ton coal * 24 hours/day = <u>35,709.9 lb SO_2/day</u>
NO_X – 11.03 tons coal/hour * 22 lb NO_X/ton coal * 24 hours/day = <u>5,823.7 lb NO_X/day</u>
PM_{10} – 11.03 tons coal/hour * 19.92 lb PM_{10}/ton coal * (1-87.5/100) * 24 hours/day =
<u>659.07 lb PM_{10}/day</u>

As previously mentioned, the refined meteorological dataset for this analysis was originated by the University of Missouri – Columbia. The results of the refined analysis for Mingo, Hercules, and Upper Buffalo are presented in Table 9.12, including the 8th highest (98 percentile) values. Also, as with the department's analysis of the University of Missouri – Columbia's boiler, the

same PM_{10} direct conversion to PMF calculation methodology was utilized to determine visibility impacts in CALPOST.

Table 9.12: Marshall Municipal Utilities Refined Analysis Results

Facility	Class I Area	Max M2 Impact	98% M2 Impact	Days > 0.5 (M2)	Max M6 Impact	98% M6 Impact	Days >0.5 (M6)	Year
Marshall	Mingo	0.371	0.133	0	0.355	0.104	0	2001
Marshall	Mingo	1.487	0.143	2	0.698	0.143	2	2002
Marshall	Mingo	0.429	0.160	0	0.436	0.143	0	2003
Marshall	Hercules	1.074	0.263	6	0.453	0.235	0	2001
Marshall	Hercules	0.99	0.210	2	0.523	0.173	1	2002
Marshall	Hercules	0.495	0.432	0	0.420	0.211	0	2003
Marshall	Upper Buffalo	0.400	0.184	0	0.416	0.159	0	2001
Marshall	Upper Buffalo	0.474	0.187	0	0.341	0.175	0	2002
Marshall	Upper Buffalo	0.747	0.395	2	0.442	0.236	0	2003

The results demonstrate that the source at Marshall Municipal Utilities does not exceed the 98^{th} percentile visibility impact threshold of 0.5 deciview even if the more conservative CALPOST Method 2 methodology is used.

9.3.5 Columbia Municipal Power Plant

The emission rates used for the BART-eligible unit (Boiler #7– EP02) at Columbia were generated by using the maximum boiler heat input (371 MMBTU/hr) and the minimum heat content for the coal used over the last five years (13,304 BTU/lb in 2004). This produced a maximum hourly design rate of 13.94 tons coal / hour. This design rate was multiplied by the highest annual emission factor for the last five years for each pollutant of interest: SO_2 – 47.42 lb SO_2/ton coal, 14.74 lb NO_X/ton coal, and 13.2 lb PM_{10}/ton coal (pre-control). For PM_{10}, the uncontrolled emissions were multiplied by (1-Control Efficiency%/100) to reflect the operation of a cyclone/baghouse combination. The resultant emissions were:

SO_2 -- 13.94 tons coal/hour * 47.42 lb SO_2/ ton coal * 24 hours/day = <u>15,868.5 lb SO_2/day</u>

NO_X – 13.94 tons coal/hour * 14.74 lb NO_X/ton coal * 24 hours/day = <u>4,932.5 lb NO_X/day</u>

PM_{10} – 13.94 tons coal/hour * 13.2 lb PM_{10}/ton coal * (1-99.75/100) * 24 hours/day =

<u>11.04 lb PM_{10}/day</u>

As previously mentioned, the refined meteorological dataset for this analysis was originated by the University of Missouri – Columbia. The results of the refined analysis for Mingo, Hercules, and Upper Buffalo are presented in Table 9.13 including the 8^{th}-highest (98 percentile) values. The same PM_{10} direct conversion to PMF calculation methodology was utilized to determine visibility impacts in CALPOST as with the other boilers reviewed.

Table 9.13: Columbia Municipal Utilities Refined Analysis Results

Facility	Class I Area	Max M2 Impact	98% M2 Impact	Days > 0.5 (M2)	Max M6 Impact	98% M6 Impact	Days >0.5 (M6)	Year
Columbia	Mingo	0.137	0.090	0	0.200	0.074	0	2001
Columbia	Mingo	1.337	0.102	1	0.645	0.095	1	2002
Columbia	Mingo	0.265	0.166	0	0.244	0.152	0	2003
Columbia	Hercules	0.467	0.183	0	0.411	0.130	0	2001
Columbia	Hercules	0.255	0.137	0	0.196	0.102	0	2002
Columbia	Hercules	0.343	0.171	0	0.232	0.119	0	2003
Columbia	Upper Buffalo	0.465	0.098	0	0.241	0.094	0	2001
Columbia	Upper Buffalo	0.401	0.090	0	0.301	0.091	0	2002
Columbia	Upper Buffalo	0.211	0.147	0	0.152	0.100	0	2003

The results demonstrate that the source at Columbia Municipal Power Plant does not exceed the 98^{th} percentile visibility impact threshold of 0.5 deciview even if the more conservative CALPOST Method 2 methodology is used.

9.3.6 BASF Corporation - Palmyra

The emission rates used for the BART-eligible units (124,000 Gallon Nitric Acid Tank – PR08, D Incinerator – TC01, A Incinerator – PR53, B Incinerator – PR54, and 2 Natural Gas Fired Boilers – UTIL07) at BASF were generated by utilizing the potential throughput for each unit and the maximum emission factor over the last five years. The remaining units at this facility were installed outside the BART timeframe or did not emit one of the visibility impairing pollutants. Unit PR08 has NO_X emissions from two components: working loss and breathing loss. The working loss throughput was calculated by assessing the maximum amount of acid moved through the tank in the last five years (2,130,000 gallons in 2005) and dividing by the number of hours acid was "worked" in the tank (5,544 hours – 24 hours, 7 days, 33 weeks). This results in 384.1 gallons/hour. The emission factor is 0.16 lb NO_X /1000 gallons. The resultant emission calculation is:

NO_X – 0.3841 1000 gal acid/hour * 0.16 lb NO_X/1000 gallon * 24 hours/day =
<u>1.5 lb NO_X/day</u>

The breathing loss was calculated using the tank capacity multiplied by the appropriate emission factor.

NO_X – 124 1000 gal capacity * 1.94 lb NO_X/1000 gallons / 365 days/year =
<u>0.66 lb NO_X/day</u>

The emissions from the D Incinerator (TC01) utilized the maximum hourly design rate of material (7.75 tons/hour) and the maximum emission factor for the last five years for each pollutant – all were 2005. The emissions calculations are below:

SO_2 -- 7.75 tons/hour * 3.841 lb SO_2/ ton * 24 hours/day = <u>714.4 lb SO_2/day</u>
NO_X – 7.75 tons/hour * 1.662 lb NO_X/ton * 24 hours/day = <u>309.1 lb NO_X/day</u>
PM_{10} – 7.75 tons/hour * 1.923 lb PM_{10}/ton * 24 hours/day = <u>357.7 lb PM_{10}/day</u>

The emissions from the A Incinerator (PR53) utilized the maximum hourly design rate of material (25 tons/hour) and the maximum emission factor for the last five years for each applicable pollutant – both were 2006. The emissions calculations are below:

NO_X – 25 tons/hour * 8.90 lb NO_X/ton * 24 hours/day = <u>5,340.0 lb NO_X/day</u>
PM_{10} – 25 tons/hour * 1.35 lb PM_{10}/ton * 24 hours/day = <u>810.0 lb PM_{10}/day</u>

The emissions from the B Incinerator (PR54) utilized the maximum hourly design rate of material (25 tons/hour) and the maximum emission factor for the last five years for each applicable pollutant – NO_X – 2004 and PM_{10} - 2005. The emissions calculations are below:

NO_X – 25 tons/hour * 3.99 lb NO_X/ton * 24 hours/day = <u>2,394.0 lb NO_X/day</u>
PM_{10} – 25 tons/hour * 0.588 lb PM_{10}/ton * 24 hours/day = <u>352.5 lb PM_{10}/day</u>

The emissions from the two natural gas-fired boilers (UTIL07) utilized the maximum heat input of the two boilers (232.5 MMBTU/hour) along with a heat content of 1,050 MMBTU/MMCF for natural gas to arrive at 0.2214 MMCF/hour. The emission factor (140 lb NOx / MMCF) was obtained from EPA's AP-42 guidance document. The emissions calculations are below:

NO_X – 0.2214 MMCF/hour * 140 lb NO_X/MMCF * 24 hours/day = <u>743.9 lb NO_X/day</u>

As previously mentioned, the refined meteorological dataset for this analysis was originated by the University of Missouri – Columbia. The results of the refined analysis for Mingo, Hercules, and Upper Buffalo are presented in Table 9.14 including the 8^{th}-highest (98 percentile) values. The same PM_{10} direct conversion to PMF calculation methodology was utilized to determine visibility impacts in CALPOST as with the other boilers reviewed.

Table 9.14: BASF Corporation Refined Analysis Results

Facility	Class I Area	Max M2 Impact	98% M2 Impact	Days > 0.5 (M2)	Max M6 Impact	98% M6 Impact	Days >0.5 (M6)	Year
BASF	Mingo	0.152	0.062	0	0.100	0.065	0	2001
BASF	Mingo	0.260	0.059	0	0.153	0.050	0	2002
BASF	Mingo	0.088	0.040	0	0.080	0.038	0	2003
BASF	Hercules	0.210	0.032	0	0.121	0.022	0	2001
BASF	Hercules	0.097	0.020	0	0.081	0.018	0	2002
BASF	Hercules	0.170	0.043	0	0.082	0.030	0	2003
BASF	Upper Buffalo	0.198	0.024	0	0.119	0.012	0	2001
BASF	Upper Buffalo	0.059	0.022	0	0.059	0.018	0	2002
BASF	Upper Buffalo	0.155	0.028	0	0.075	0.020	0	2003

The results demonstrate that the BART-eligible sources at BASF Corporation - Palmyra Plant do not exceed the maximum visibility impact threshold of 0.5 deciview even if the more conservative CALPOST Method 2 methodology is used.

9.3.7 Doe Run - Buick

The emission rates used in this visibility sensitivity for the BART-eligible unit (Blast Furnace - Main Stack EP08) at Doe Run Buick were generated using the 2005 construction permit limits for this source. Specifically, the facility-wide SO_2 limit was utilized, while the unit specific limits for NOx and PM10 were used. The emission rates are as follows:

SO_2 -- <u>18,630.1 lb SO_2/day</u>

NO_X – <u>20.6 lb NO_X /day</u>

PM_{10} – <u>184.8 lb PM_{10}/day</u>

The refined meteorological dataset for this sensitivity was originated by the University of Missouri – Columbia. The results of the refined analysis for Mingo are presented in Table 9.15 including the 8th highest (98 percentile) values. Also, as with the department's analysis of the University of Missouri – Columbia's boiler, the same PM_{10} direct conversion to PMF calculation methodology was utilized to determine visibility impacts in CALPOST.

Table 9.15: Doe Run Buick Refined Sensitivity Results

Facility	Class I Area	Max M2 Impact	98% M2 Impact (8th high)	Days > 0.5 (M2)	Max M6 Impact	98% M6 Impact (8th high)	Days >0.5 (M6)	Year
DR Buick	Mingo	1.007	0.230	2	0.643	0.233	2	2001
DR Buick	Mingo	0.714	0.246	2	0.365	0.171	0	2002
DR Buick	Mingo	0.424	0.252	0	0.397	0.203	0	2003

These results demonstrate that the current set of emissions at Doe Run – Buick will not have an adverse impact on the Mingo Refuge and bolster the finding of no additional SO_2 control necessary for BART.

9.3.8 Holcim - Clarksville

Prior to the March 2008 regional haze state implementation plan submittal, there were two different modeling analyses conducted for Holcim – Clarksville. The first evaluation utilized SO_2 and NO_X emissions from the calculation documented below (tons clinker per hour X lb pollutant / ton clinker). The other analysis utilized a maximum 24-hour actual emission rate for SO_2 and NO_X from 2004-07 based on Holcim's continuous emission monitoring system.

The emission rates used in this analysis for the largest BART-eligible units at Holcim – Clarksville (EP14 – Main Stack) were generated by using the maximum clinker throughput for the kiln (175 tons/hour) and the maximum emission factors over the last five years. The highest annual emission factor for the last five years for each pollutant of interest is: SO_2 – 22.97 lb SO_2/ton clinker, 13.89 lb NO_X/ton clinker, and 0.22 lb PM_{10}/ton clinker. The resultant emissions were:

SO_2 -- 175 tons clinker/hour * 22.97 lb SO_2/ ton clinker * 24 hours/day = 96,474.0 lb SO_2/day

NO_X – 175 tons clinker/hour * 13.89 lb NO_X /ton clinker * 24 hours/day = 58,338.0 lb NO_X /day

PM_{10} – 175 tons clinker/hour * 0.22 lb PM_{10}/ton coal * 24 hours/day = 924.0 lb PM_{10}/day

The remaining emission points (mostly handling of materials) were only PM_{10} emissions and were calculated based on maximum hourly design rate and emission factor for the particular operation. These emission points are further documented in Appendix I.

As previously mentioned, the refined meteorological dataset for this analysis was originated by the University of Missouri – Columbia. The results of the refined analysis for Mingo, Hercules, and Upper Buffalo are presented in Table 9.16 including the 8^{th}-highest (98 percentile) values. The same PM_{10} direct conversion to PMF calculation methodology was utilized to determine visibility impacts in CALPOST as with the other boilers reviewed.

Table 9.16: Holcim - Clarksville Refined Analysis Results

Facility	Class I Area	Max M2 Impact	98% M2 Impact	Days > 0.5 (M2)	Max M6 Impact	98% M6 Impact	Days >0.5 (M6)	Year
Holcim	Mingo	1.975	**1.214**	26	1.378	**0.924**	23	2001
Holcim	Mingo	3.135	**1.088**	24	1.784	**0.834**	19	2002
Holcim	Mingo	1.861	**1.042**	18	1.719	**0.734**	15	2003
Holcim	Hercules	1.607	**0.650**	8	1.274	0.480	7	2001
Holcim	Hercules	2.699	**0.667**	11	1.758	**0.799**	10	2002
Holcim	Hercules	1.847	**0.804**	16	1.147	**0.626**	13	2003
Holcim	Upper Buffalo	1.543	0.389	7	1.101	0.382	5	2001
Holcim	Upper Buffalo	2.847	**0.557**	10	1.955	0.465	7	2002
Holcim	Upper Buffalo	1.502	**0.776**	15	1.309	**0.580**	12	2003

The refined modeling impacts from Holcim – Clarksville exceed the 0.5 deciview threshold for all three Class 1 areas for both the Method 2 and the Method 6 CALPOST methodology. Therefore, the department contacted Holcim to pursue control of SO_2 and NO_X for BART. The PM_{10} impact on visibility is less than 1 percent and does not constitute enough impact to pursue control. Holcim initially responded (prior to the March 2008 submittal) that they were in the process of retrofitting the kiln under permit #082007-019 that requires them to install a mid-kiln firing system for NO_X control. As a point of reference, the department determined that mid-kiln

firing was equivalent to a 30 percent reduction from 1990 cement kiln NO_X emissions based on EPA information provided during the development of the NO_X SIP call.

After the March 2008 SIP submittal, Holcim provided additional information detailing the maximum 24-hour SO_2 and NO_X emissions using continuous emission monitoring (CEM) data. Holcim installed the CEM data in 2004, began collection of hourly emission data, and has maintained the necessary quality assurance measures to ensure accuracy of this data. The use of maximum 24-hour emission rates is the preferred methodology for determination of visibility impacts from BART sources (if available). The department utilized the maximum 24-hour emission rates provided by Holcim with the necessary filling of missing hourly data. The PM_{10} emission rates used in the new analysis were identical to the previous screening and refined modeling analyses. The resultant emissions obtained from the CEM data were:

SO_2 – 4,900.95 lb SO_2/hr = <u>117,622.7 lb SO_2/day</u> on 12/2/2004
NO_X – 3049.39 lb NO_X/hr = <u>73,185.3 lb NO_X /day</u> on 11/24/2007

These emissions were modeled using the refined analysis method described above. The Method 6 results are presented in Table 9.17.

Table 9.17: Holcim - Clarksville Post-Submittal Refined Analysis Results

Facility	Class I Area	Max M6 Impact	98% M6 Impact (8th high)	Days >0.5 (M6)	Year
Holcim	Mingo	1.685	**1.124**	26	2001
Holcim	Mingo	2.183	**1.018**	25	2002
Holcim	Mingo	2.063	**0.894**	23	2003
Holcim	Hercules	1.534	**0.595**	9	2001
Holcim	Hercules	2.129	**0.968**	11	2002
Holcim	Hercules	1.391	**0.769**	18	2003
Holcim	Upper Buffalo	1.331	0.465	7	2001
Holcim	Upper Buffalo	2.364	**0.572**	9	2002
Holcim	Upper Buffalo	1.577	**0.716**	17	2003

Based on confirmation of the visibility impacts over the 0.5 deciview impact, Holcim provided a BART proposal in late April 2008 that included inherent scrubbing (no additional control) for SO_2 and existing low NO_X burners and cement kiln dust insufflation along with the mid-kiln firing of tires at 12 percent fuel rate for NO_X control. The mid-kiln firing of tires was estimated

by Holcim to provide a 20 percent reduction from existing NO_X emission levels. This submittal is included as part of Appendix N.

Based on the review of the Holcim submittal, the department requested additional SO_2 control information regarding scrubber problems with opacity and installation cost, cost evaluation of "local" fuels (specifically, switching from current petroleum coke at 6 percent sulfur to medium sulfur coal), and detailed information regarding sulfur balance of the kiln inputs from fuel and other raw materials and outputs as sulfur in product, solid waste streams, and stack exhaust gases (SO_2). The department was specifically interested in a partial control of the exhaust stream with a scrubber that would include a by-pass for part of the stream to help eliminate the opacity associated with reduced temperature after SO_2 scrubbing.

Holcim provided revised submittals in June and July 2008 (Appendix O and Appendix P, respectively) that addressed the partial stream scrubbing question for the kiln and provided sufficient information for the ultimate finding of emissions that would satisfy BART for the kiln operation at Clarksville. Holcim proposed a 20 percent reduction of NO_X and a 23 percent reduction of SO_2 from their maximum 24-hour emission rates modeled. The proposal also requested this limit be expressed as a 30-day rolling average. Based on a comprehensive review of these submittals along with visibility modeling of the impacts from this source, the department concluded that the mid-kiln firing of tires (using 12 percent total heat input substitution) and a switch from petroleum coke as the primary kiln fuel to 3 percent sulfur coal (along with the tire-derived fuel for NO_X control) would constitute BART for this source. However, the department did not agree with the emission limits proposed by Holcim. Specifically, the department did not agree to the use of the percentage reduction from the maximum 24-hour emission rate when using a thirty-day rolling average.

The SO_2 finding was based primarily on the economic evaluation of several different control scenarios for the kiln including both wet and dry scrubbing of the kiln exhaust gas. The department found the overall net cost per ton of cement produced (~$15-20/ton) was excessive and would have seriously compromised the Clarksville kiln's ability to compete in the cement production market. The fuel switch provided a significant amount of emission reductions at a

cost of approximately \$3/ton cement produced. The overall cost per ton SO_2 reduced was calculated as \$1,148/ton removed. The NO_X finding was based on information provided by Cinar (kiln design contractor for Holcim) regarding NO_X emission rates when burning tire-derived fuel and the department's serious concern over the use of selective non-catalytic reduction on the world's largest long wet cement kiln. The increased certainty of the mid-kiln firing of tires, along with the use of low-NO_X burners and cement kiln dust insufflation, provide a firm basis for the finding of NO_X BART at Clarksville. In addition, this reduction of emissions was to have very little additional cost for the plant due to the planned installation of the mid-kiln firing project. The department findings result in a 20 percent reduction of NO_X and a 27 percent reduction of SO_2 from the maximum 30-day average emissions using the CEM data. As provided in the presumptive BART finding for utilities, the emission limits are expressed as 30-day rolling averages of 42,287 pounds NO_X/day and 58,787 pounds SO_2/day. The calculation of these averages will include all hours when the kiln is not operating and those emissions for both pollutants will be entered as zero pounds. Detailed SO_2 cost spreadsheets along with calculations of emission reductions are included in Appendix Q.

Refined visibility modeling was conducted with the BART limits prescribed by the department using the previous refined modeling analysis as a baseline to determine the extent of visibility improvement for each of the three impacted Class I areas. The results are provided in Table 9.18.

Table 9.18: Holcim - Clarksville BART Limit Refined Analysis Results

Facility	Class I Area	Max M6 Impact	98% M6 Impact (8^{th} high)	Days >0.5 (M6)	Year
Holcim	Mingo	0.963	**0.598**	13	2001
Holcim	Mingo	1.254	**0.532**	8	2002
Holcim	Mingo	1.094	0.471	7	2003
Holcim	Hercules	0.800	0.331	3	2001
Holcim	Hercules	1.163	0.499	7	2002
Holcim	Hercules	0.734	0.412	4	2003
Holcim	Upper Buffalo	0.697	0.236	4	2001
Holcim	Upper Buffalo	1.293	0.300	3	2002
Holcim	Upper Buffalo	0.825	0.370	3	2003

These results demonstrate less than the 0.5 deciview threshold for the 98^{th} percentile visibility impact at the Hercules Glade and Upper Buffalo Wilderness Areas. Further, great improvement

at the more proximate Mingo National Wildlife Refuge was also demonstrated. The highest 98th percentile impact was in 2001 and this impact was reduced 47 percent from the original refined modeling estimate.

The BART finding was provided to Holcim on August 18, 2008, along with the rationale for the finding and a draft consent agreement drafted by the department to codify the emission requirements for Holcim – Clarksville (also included in Appendix R). Subsequent comments provided by both Holcim and EPA Region VII necessitated some changes to the draft. In December 2008, Holcim informed the department of its intention to stop production at the Clarksville facility after the 1st quarter of 2009. A mutual decision was made to finalize the agreement in the event that Holcim would need to restart the Clarksville kiln operation in the near future. However, at this point, there has been no indication that the kiln will be operated further. The final consent agreement was signed by the department on April 14, 2009, and is included in Appendix S for inclusion in the regional haze State Implementation Plan.

As discussed previously, the EPA has found that, as a whole, the CAIR cap-and-trade program improves visibility more than implementing BART in states affected by CAIR. The state of Missouri has opted to participate in the CAIR program under part 96 AAA-EEE and, therefore, the CAIR EGU sources are not required to install, operate, and maintain BART for SO_2 or NO_X.

In summary, the State of Missouri has identified one BART-eligible source in Missouri that entered into a consent agreement with the department to limit emissions of SO_2 and NO_X. This agreement is the mechanism for enforcement of the BART requirements for this source. All other sources were examined and the findings were as follows:

1) sources were not operating or have a federally-enforceable construction permit to shutdown the applicable units,
2) sources were Clean Air Interstate Rule units (EGUs) that were determined to have installed BART based on their CAIR status,
3) one source was found to have been issued two subsequent Prevention of Significant Deterioration permits with a BACT finding, or

4) units were eliminated based on less than the threshold (0.5 deciview) impact from a screening analysis (maximum impact) or a refined analysis for four facilities (98 percent impact)

10.0 REASONABLE PROGRESS GOALS

10.1 Reasonable Progress Goal Requirements

40 CFR 51.308(d)(1) requires Missouri to establish RPGs for each Class I area within the state (in dv) that provide for reasonable progress towards achieving natural visibility. In addition, EPA released guidance on June 1, 2007 to use in setting RPGs (Appendix N). The goals must provide improvement in visibility for the most impaired days, and ensure no degradation in visibility for the least impaired days over the plan period. The state must also provide an assessment of the number of years it would take to attain natural visibility conditions if improvement continues at the rate represented by the RPG.

The EPA guidance referenced above describes the RPG development process as follows:

> *RPGs should be initially developed considering available control measures as evaluated using the statutory factors. Based on emission reductions anticipated from the resulting control strategy for all visibility impairing pollutants, the state should ensure that the RPGs define visibility conditions at, or better than, conditions based on the uniform rate of progress. If a state finds that its initial RPG will not result in visibility improvement equal to or better than the uniform rate of progress, then the state should reconsider available control measures, and additional measures should be evaluated as appropriate. The RPGs should then be revised based upon a more stringent suite of controls.*

The "statutory factors" that the state must consider are identified in 40 CFR 51.308(d)(1)(i)(A) as:

a) The costs of compliance,
b) The time necessary for compliance,
c) The energy and non-air quality environmental impacts of compliance, and
d) The remaining useful life of existing sources that contribute to visibility impairment.

The state must demonstrate how these factors were taken into consideration in selecting the goal

for its mandatory Class I areas.

10.2 MISSOURI REASONABLE PROGRESS GOAL

In determining reasonable progress goals, CAA §169A(g)(1) requires states to take into consideration four factors, however, flexibility in consideration of factors may be used. The EPA guidance indicates that

> *…the factors could be used to select which sources or activities should or should not be regulated, or they could be used to determine the level or stringency of control, if any, for selected sources or activities, or some combination of both. The factors may be considered both individually and/or in combination. As noted in section 4.1, given the significant emissions reductions that we anticipate to result from BART, the CAIR, and the implementation of other CAA programs, these reductions may be all that is necessary to achieve reasonable progress in the first planning period for some States. Also, as noted in section 4.2, it is not necessary for you to reassess the reasonable progress factors for sources subject to BART for which you have already completed a BART analysis.*

Missouri's four-factor analysis for this Regional Haze Plan is achieved using the factor analyses conducted by EPA, CENRAP and other RPOs. Chapter 11, the Long-Term Strategy Plan, identifies the control measures necessary to achieve the Reasonable Progress Goals. The BART analysis for Missouri also contributes to the four-factor analysis.

10.2.1 Cost and time necessary for compliance factor analysis by EPA

The analyses in this Regional Haze Plan demonstrate that the 2018 visibility goals for Mingo and Hercules Glades have been largely achieved through EGU emission reductions. These reductions will be energy and environmental neutral, but are clearly most effective in improving haze levels. In addition, controls under CAIR are effective for a considerable lifetime of the operating units. A discussion in the CAIR rule highlighted below (70 FR 25197) addresses their analysis of reasonable progress factors of cost and time necessary for compliance.

> *From past experience in examining multi-pollutant emissions trading programs for SO_2 and NO_X, EPA recognized that the air pollution control retrofits that*

result from a program to achieve highly cost-effective reductions are quite significant and can not be immediately installed. Such retrofits require a large pool of specialized labor resources, in particular, boilermakers, the availability of which will be a major limiting factor in the amount and timing of reductions.

Also, EPA recognized that the regulated industry will need to secure large amounts of capital to meet the control requirements while managing an already large debt load, and is facing other large capital requirements to improve the transmission system. Furthermore, allowing pollution control retrofits to be installed over time enables the industry to take advantage of planned outages at power plants (unplanned outages can lead to lost revenue) and to enable project management to learn from early installations how to deal with some of the engineering challenges that will exist, especially for the smaller units that often present space limitations.

Based on these and other considerations, EPA determined in the NPR that the earliest reasonable deadline for compliance with the final highly cost-effective control levels for reducing emissions was 2015 (taking into consideration the existing bank of title IV SO_2 *allowances). First, the Agency confirmed that the levels of* SO_2 *and* NO_X *emissions it believed were reasonable to set as annual emissions caps for 2015 lead to highly cost-effective controls for the CAIR region.*

Once EPA determined the 2015 emissions reductions levels, the Agency determined a proposed first (interim) phase control level that would commence January 1, 2010, the earliest the Agency believed initial pollution controls could be fully operational (in today's final action, the first NO_X *control phase commences in 2009 instead of in 2010, as explained in detail in section IV.C). The first phase would be the initial step on the slope of emissions reductions (the glide-path) leading to the final (second) control phase to commence in 2015. The EPA determined the first phase based on the feasibility of installing the necessary emission control retrofits, as described in section IV.C.*

Although EPA's primary cost-effectiveness determination is for the 2015 emissions reductions levels, the Agency also evaluated the cost effectiveness of the first phase control levels to ensure that they were also highly cost effective. Throughout this preamble section, EPA reports both the 2015 and 2010 (and 2009 for NO_X) cost-effectiveness results, although the first phase levels were determined based on feasibility rather than cost effectiveness. The 2015 emissions reductions include the 2010 (and 2009 for NO_X) emissions reductions as a subset of the more stringent requirements that EPA is imposing in the second phase.

10.2.2 Cost analysis by CENRAP

CENRAP, assisted by Alpine Geophysics, conducted additional cost analysis for its 10 Class I areas including Mingo and Hercules Glades areas in Missouri. Alpine primarily looked at controls on EGUs; Industrial, Commercial and Institutional (ICI) boilers; internal combustion engines; and cement kilns. Most of the Missouri facilities identified in the analysis were EGUs already participating in federal CAIR rule. The analysis also provided recommendations on additional controls for non-EGUs, which were considered but not adopted due to the following reasons:

- Proposed controls are not cost effective – over $2,000 per ton of SO_2 or NO_X
- Emissions below the threshold limit of 100 tons
- Sources passed the BART screening analysis
- Sources already installed controls required by the NO_X SIP Call

10.2.3 Four-factor analysis by MRPO

In addition to the EPA and Alpine's analyses, the MRPO and the Minnesota Pollution Control Agency published a report on the four-factor analysis (referred to as the "4-factor report"). The report looked at the factors in a nine-state area (Minnesota, Wisconsin, Michigan, Indiana, Illinois, Missouri, Iowa, North Dakota, and South Dakota.). The 4-factor report primarily looked at controls on EGUs; ICI boilers; reciprocating engines and turbines; and mobile sources. Tables summarizing the nine-state impacts are listed in the appendices of this published report.

10.2.3.1 Cost of compliance and remaining useful life

The 4-factor report looked at the cost effectiveness of additional SO_2 and NO_X emissions reduction using two possible control strategies categorized as EGU1 and EGU2. The EGU1 scenario would cap EGU NO_X emissions at 0.10 lb/MMBtu of fossil fuel consumption and SO_2 would be limited to 0.15 lb/MMBtu of fossil fuel consumption at EGUs. The EGU2 caps are more stringent at 0.07 lb/MMBtu and 0.10 lb/MMBtu of fossil fuel consumption for NO_X and SO_2, respectively. The caps are not enforced at the unit level but represent a proposed region wide average emission rate to be met through a trading program.

Missouri has concluded that additional controls from ICI boilers is unwarranted. Costs across the nine-state region, in terms of dollars per deciview, exceed two billion dollars. Similar reasons apply to other point sources, such as reciprocating engines and combustion turbines. Because Missouri has determined that additional emission controls are not required based on the cost of compliance, it is not necessary to determine the remaining useful life of each unit.

10.2.3.2 Energy and non-air quality environmental impacts of compliance

The 4-factor report also demonstrates the energy and non-air quality environmental impacts of controlling emissions. In the nine-state region, carbon dioxide emissions are projected to increase from 3,766,000 tons/year to 5,302,000 tons/year due to the EGU1 and EGU2 controls, respectively.

An additional 1,128,000 – 1,919,000 gallons of wastewater per year is projected to be produced by 2018 in the nine-state region under the EGU1 and EGU2 controls, respectively. The 4-factor report states that the additional gallons would be treated in existing facilities. The cost of treating the additional wastewater and the likelihood of new facilities increases the costs of compliance.

The nine-state region would also incur a projected increase in solid waste production by 2018 of 347,000 – 538,000 tons as part of the EGU1 and EGU2 controls, respectively. The process of siting a new landfill can take decades.

10.2.4 Missouri reasonable progress goals

It is reasonable to implement CAIR as EPA intended during the first regional haze planning period. Missouri's four-factor analysis finds that ongoing air pollution control programs, including CAIR, BACT, and BART, are sufficient to meet the 2018 Uniform Rate of Progress for the Mingo and Hercules Glades Class 1 areas. Missouri has adopted EPA's CAIR cap and trade program and will participate fully in the SO_2, annual NO_X, and ozone season NOx trading programs. Missouri's intent is to allow the market forces of the CAIR cap and trade program to drive the installation and operation of cost efficient controls.

Figures 8.1a and 8.1.b. show the Uniform Rate of Progress (URP) and modeled 2018 visibility projections. The 2018 projections were below the URPs for both Missouri Class I areas. Missouri has determined that the modeled rate of visibility improvement by 2018 shown in Table 10.1 is reasonable and hereby adopts it as the RPG for the listed Class I areas. Table 10.1 provides a Uniform Rate of Progress and Reasonable Progress for Class I areas in Missouri.

Table 10.1: Uniform Rate of Progress and Reasonable Progress Goals for Class I areas in Missouri

Class I Area	2000/2004 Baseline Conditions (dv)	2018 URP Point (dv)	2018 Modeled Predictions (dv)	2064 Natural Background Conditions (dv)	Deciview Improvement Needed by 2018 assuming RPG	Progress Annually to 2018 assuming RPG (dv)
Mingo	28.02	24.37	23.71	12.40	4.31	0.308
Hercules Glades	26.75	23.14	23.06	11.30	3.69	0. 264

To ensure that the emissions from new stationary sources and major modifications will be consistent with making reasonable progress toward the national visibility goal, Missouri has a requirement to do a visibility impairment evaluation as part of the major construction permitting process.

10.3 CONSULTATION

In determining a reasonable progress rate for each Class I area discussed above, Missouri has consulted with FLMs and the other states/tribes, which (are) reasonably anticipated to cause or

contribute to visibility impairment in each of these Class I areas. A description of the consultation process is provided in Appendix E, *United States Central Class I Areas Consultation Plan*, Missouri Department of Natural Resources, 2007. In addition, the minutes from those meetings are in Appendix U)

10.4 REPORTING

Progress will be reported to the EPA every five years in accordance with 51.308 (g).

11.0 LONG-TERM STRATEGY TO REACH REASONABLE PROGRESS GOALS

11.1 LONG-TERM STRATEGY REQUIREMENTS

40 CFR 51.308(d)(3) requires Missouri to submit a long-term strategy that addresses regional haze visibility impairment for each mandatory Class I federal area within and outside the state, which may be affected by emissions from within the state. The long-term strategy must include enforceable emissions limitations, compliance schedules and other measures necessary to achieve the RPGs established by states/tribes where the Class I areas are located. This chapter describes how Missouri meets the long-term strategy requirements.

11.2 CONSULTATION

Missouri will continue to coordinate and consult with the consultation stakeholders during the development of future progress reports and plan revisions, as well as during the implementation of programs having the potential to contribute to visibility impairment in the mandatory Class I areas. Face to face meetings will be held if deemed necessary. Otherwise, consultation will be in the form of conference calls and/or letter or email correspondence. The Central Class I areas consultation will be initiated through the Central Class I areas contacts listed in the consultation plan (Appendix E).

Missouri also participated in the consultation processes for Arkansas, Oklahoma and Minnesota; and will continue to participate in other consultation processes in response to any other states that request our participation.

11.3 SHARE OF EMISSION REDUCTIONS

40 CFR 51.308(d)(3)(ii) requires Missouri to demonstrate that its implementation plan includes all measures necessary to obtain its fair share of emission reductions needed to meet RPGs.

Missouri relied on technical analyses developed by CENRAP and additional weight of evidence analysis developed as part of consultation planning to determine contributing states (Appendix E). Nine states, including Missouri, Arkansas, Kentucky, Illinois, Indiana, Ohio, Oklahoma,

Tennessee and Texas, were identified as contributing to visibility in Mingo and/or Hercules Glades Class I areas. The modeling demonstration has shown that the emission reductions from these contributing states are sufficient to achieve RPGs in Missouri's Class I areas.

Current visibility is estimated from monitored components of $PM_{2.5}$ and coarse mass. Models are used in a relative sense to estimate how current concentrations respond to emission reduction measures. Data analysis is used to identify source categories and regions. Current concentrations of particulate matter components are adjusted by the relative modeled response to estimate concentrations at the end the first implementation period in 2018. Future visibility is estimated from estimated component concentrations of $PM_{2.5}$ and PM_{10} at the end of the first implementation period. The difference between present visibility and future estimated visibility is compared with the RPGs to determine if the goal is met. The CENRAP technical analyses on visibility conditions and RPGs projections can be found in Appendix F. All applicable measures reflected in the modeling demonstration and weight of evidence analysis have been incorporated in the state's long-term strategy. Section 11.4 provides information on these control measures.

11.4 LONG-TERM STRATEGY COMPONENTS

40 CFR 51.308(d)(3)(v) requires Missouri to consider several factors in developing its long-term strategy. The ongoing air pollution control programs described in section 11.4.1. below were used in the modeling demonstration to show that Missouri Class I Areas meet the 2018 RPG. Additional controls beyond the RPG modeling demonstration that may be considered for use in the long term strategy at a future date are described in section 11.4.2 below.

11.4.1 Ongoing air pollution control programs – "on the books" controls

40 CFR 51.308(d)(3)(v)(A) requires states to consider emission reductions from ongoing pollution control programs. The NO_X and SO_2 emissions reductions resulting from these ongoing programs will help improve air quality throughout the state of Missouri.

Missouri used the following "on the books" control programs in the modeling demonstration to meet the RPG requirements as presented in Table 10.1 of this Regional Haze Plan. The substantial improvements in visibility impairment at the Mingo site for the worst 20 percent days

from 2002 (141 Mm-1) to 2018 (96 Mm-1) is primarily due to reductions in SO_4 (35 Mm-1 improvement) from elevated point sources (Figures E-7a through E-7d of the TSD). Elevated point sources also contribute over half to the total extinction for the worst 20 percent days at Hercules Glades in 2002 (Figures E-6a and E-6b of the TSD). Going from 2002 to 2018 the contributions due to elevated point sources (essentially CAIR and NO_X SIP call), on-road mobile and non-road mobile are reduced substantially, over 25 Mm-1.

11.4.1.1 Clean Air Interstate Rule (CAIR)

On March 10, 2005, EPA signed the CAIR, following three years modeling study and cost analysis on SO_2 and NO_X controls.

As required by CAIR, Missouri developed draft rules through the workgroup process.

The rules were presented for public hearing at the December 7, 2006, MACC Meeting and they were adopted at the February 1, 2007, MACC Meeting. The rules establish a cap and trade system for NO_X and SO_2 emissions, and Missouri sources will be included in the national program. The state rules are 10 CSR 10-6.362 Clean Air Interstate Rule Annual NO_X Trading Program and 10 CSR 10-6.366 Clean Air Interstate Rule SO_X Trading Program. The state rules include schedules for compliance, sources affected by the rule and emissions limitations.

Table 11.1 summarizes the NO_X emissions cap for each unit for each calendar year between 2009-2014 and 2015 and beyond. Table 11.2 summarizes the SO_2 emissions cap for each unit for each calendar year between 2010-2014 and 2015 and beyond. These rules can be found in Appendix V.

* 0.5 multiplier for CAIR allowances between 2010-2014

** 0.35 multiplier for CAIR allowances 2015 and after

The long-term strategy also includes any CAIR controls that are being undertaken in other impacting states that were identified during the Central Class I areas consultation process.

11.4.1.2 BART

Twenty-six potential BART sources have been identified.   Twenty-five have been dropped through the screening and refined analyses. The remaining source (Holcim – Clarksville) entered into a consent agreement with the Missouri Department of Natural Resources to limit emissions of SO_2 and NO_X. No other sources were found to be subject to BART and, therefore, implementation of an emissions trading program, other emission controls or other alternative measure in place of BART are not necessary. Detailed analyses can be found in Chapter 9 of the SIP.

Missouri will include BART controls proposed by the eight other impacting states in its long-term strategy. Arkansas, Oklahoma and Texas have already had their BART rules proposed. Missouri is working with these states to document the emissions reduction and control measures required from their sources. Since not all of the BART determinations are completed for other states, the five-year review will be the mechanism used to adjust the Reasonable Progress Goal based on the other states' final BART determinations.

11.4.1.3 Other federal ongoing air pollution control programs

Tier 2

Tier 2 standards are federal emission standards for passenger cars, light trucks and larger passenger vehicles. The program is designed to focus on reducing the emissions most responsible for the ozone and PM impact from these vehicles – NO_X and non-methane organic gases, consisting primarily of hydrocarbons and contributing to VOCs. The Tier 2 standards will reduce new vehicle NO_X levels to an average of 0.07 grams per mile. For new passenger cars and light duty trucks, these standards were phased in starting in 2004, and the standards were fully phased in by 2007. For heavy trucks and similar vehicles, the Tier 2 standards will be phased in beginning in 2008, with full compliance in 2009.

During the phase-in period from 2004-2007, all passenger cars and light trucks not certified to the primary Tier 2 standards had to meet an interim average standard of 0.30 g/mi NO_X. During the period 2004-2008, heavy trucks and similar vehicles not certified to the final Tier 2 standards will phase in to an interim program with an average standard of 0.20 g/mi NO_X, with those not covered by the phase-in meeting a per-vehicle standard (i.e., an emissions “cap”) of 0.60 g/mi NO_X trucks and 0.09 g/mi for similar vehicles.

Tier 4

EPA's Clean Air Nonroad Diesel Rule (Tier 4) requires stringent pollution controls on diesel engines used in industries such as construction, agriculture and mining, and it will slash sulfur content of diesel fuel. This rule is the latest in a series of actions that are designed to reduce emissions from nearly every type of diesel vehicle and equipment. This nonroad diesel program combines cleaner engine technologies with cleaner fuel – similar to the on-highway diesel program. The standards will cut emissions from nonroad diesel engines by over 90 percent. Nonroad diesel equipment, as described in this rule, currently accounts for 47 percent of diesel PM and 25 percent of NO_X from mobile sources nationwide.

Sulfur levels will also be reduced in nonroad diesel fuel by 99 percent from current levels (from approximately 3,000 parts per million (ppm) now to 15 ppm in 2010). The lower sulfur fuel will also reduce PM from engines in existing nonroad equipment. It makes it possible for engine

manufacturers to use advanced clean technologies, similar to catalytic technologies used in passenger cars. The new engine standards take effect, based on engine horsepower, starting in 2008.

11.4.1.4 NO_X SIP Call

The NO_X SIP call was designed to assist downwind ozone areas in attaining the one-hour and 8-hour ozone NAAQS by providing upwind NO_X emission control. This rulemaking was developed through the EPA's interpretation of the Ozone Transport Assessment Group recommendations and subsequent modeling and cost analysis of NO_X controls to reduce ozone transport. The final NO_X SIP call was published in the *Federal Register* on October 27, 1998.

Missouri's initial rule in response to the NO_X SIP Call, 10 CSR 10-6.*350 Emission Limitations and Emissions Trading of Oxides of Nitrogen*, was adopted by the MACC on April 24, 2003. The rule established an emission limitation of 0.25 lbs NO_X /MMBtu heat input for electric generating units in the eastern one-third of the state and a lower limit of 0.18 lb/MMBtu heat input for Labadie, Rush Island, and Meramec power plants. EGUs in the western two-third of the state were limited to an emission rate of 0.35 lbs NO_X /MMBtu of heat input. Cyclone boilers (Sibley and Asbury power plants) that burn tire-derived fuels are allowed to meet 0.68 lbs NO_X /MMBtu heat input. The compliance date was May 1, 2004.

On April 21, 2004, the EPA finalized the second phase of NO_X SIP call. Phase II of the SIP call excluded the portion known as the "coarse grid" (the western 2/3 of Missouri) from the NO_X SIP Call, defined the area of the eastern 1/3 of Missouri to include the same counties as established in 10 CSR 10-6.350, with the one exception of not including Phelps County, and revised the cap for NO_X emissions from the previous statewide budget of 114,532 tons of NO_X per ozone season to a partial state budget of 61,406 tons of NO_X per ozone season in the eastern 1/3 of Missouri. The budget assumed control levels of 0.15 lbs/MMBtu for electric generating units, 82 percent emissions reductions for large natural gas-fired stationary internal combustion engines, 90 percent emissions reductions for diesel and dual fuel stationary internal combustion engines, 60 percent emissions reductions for non-utility boilers and turbines, and 30 percent emissions reductions for cement manufacturing plants. Small cogeneration units were excluded from the

NO_X SIP Call. Small cogeneration units are units that supply one-third or less of their potential electrical output capacity, or 25 megawatts or less, to any utility power distribution system for sale.

The department's Air Pollution Control Program developed 10 CSR 10-6.360 *Control of NO_X Emissions from Electric Generating Units and Non-Electric Generating Boilers*, 10 CSR 10-6.*380 Control of NO_X Emissions from Portland Cement Kilns*, and 10 CSR 10-6.*390 Control of NO_X Emission from Large Stationary Internal Combustion Engines*. This set of three rules constitutes Missouri's response to EPA's NO_X SIP Call. These rules were presented at public hearing on April 28, 2005 and were adopted at the May 26, 2005 MACC meeting. The state rules include schedules for compliance, sources affected by the rule and emissions limitations. Table 11.3 summarizes the NO_X allowances for each unit during the ozone season.

Table 11.3: NO_X SIP Call Emissions Allocation (tons/ozone season)

11.4.2 Additional controls beyond RPG modeling demonstration

Ongoing air pollution control programs, as described in Section 11.4.1, are sufficient to meet the 2018 Uniform Rate of Progress for the Mingo and Hercules Glades Class 1 areas. These ongoing programs such as CAIR, BACT, or BART have been demonstrated to be very cost-effective in reducing the visibility in Missouri's Class I areas.

Additional controls not included in the modeling demonstration in the plan may be considered during the five-year review. A number of control strategies include SO_2/NO_X Reasonably Available Control Technology (RACT) in the St Louis $PM_{2.5}$ plan, Illinois Multi-Pollutant Strategy, regional SO_2 and NO_X control strategy proposed by Alpine Geophysics (Alpine) for CENRAP.

11.4.2.1 SO_2 and NO_X RACT in St Louis

Missouri is in the process of preparing an implementation plan to address the St. Louis $PM_{2.5}$ nonattainment problem. In addition to the development of an attainment demonstration, the $PM_{2.5}$ implementation rule requires states to develop all RACT and Reasonably Achievable Control Measures (RACM). All non-EGU SO_2 and NO_X sources were identified in the St. Louis $PM_{2.5}$ nonattainment area that had actual emissions exceeding 25 tons per year. These include large boilers, stationary internal combustion engines, two glass melting furnaces, a biosolids incinerator, a cement kiln and a lead smelter. The emission reductions associated with these sources will be determined and included in the $PM_{2.5}$ plan.

11.4.2.2 Illinois Multi-Pollutant Regulation

In 2006, a multi-pollutant standard (MPS) rule was approved by the Illinois Pollution Control Board and the Joint Committee on Administrative Rules. This multi-pollutant rule will result in measurable reduction in mercury, SO_2, and NO_X emissions. The rule targets the three largest coal-fired power plant companies in Illinois: Midwest Generation, Ameren and Dynegy. These three companies represent 88 percent of Illinois' 17,007 Megawatts of electric generating capacity from coal-fired plants. By implementation of this rule, the Illinois Environmental Protection Agency estimates the total emissions reduction from all three power companies is

233,600 tons per year of SO_2 and 61,434 tons per year of NO_X. This is a drastic improvement compared to emissions reduction achieved by the CAIR.

11.4.2.3 Regional Controls proposed by Alpine Geophysics (Alpine)

In February 2006, Alpine was contracted by CENRAP to assist in developing control strategies for CENRAP Class I areas. Based on the available cost information and the Area of Influence (AOI) analyses, Alpine proposed a methodology for constructing control strategy for both EGUs and non-EGUs. Control technologies for different industrial source categories were identified. Regional "CAIR-like" EGU controls, and sub-regional (AOI region) – Industrial, Commercial, and Institutional boilers and natural gas compressors controls – were recommended by Alpine. The final report from Alpine can be found in Appendix W.

11.4.3 Measures to mitigate the impacts of construction activities

40 CFR 51.308(d)(3)(v)(B) requires Missouri to consider measures to mitigate the impacts of construction activities. Under the NAAQS, any nonattainment area in Missouri is required to consider construction emissions as part of the general conformity rule. Missouri meets this commitment through rule 10 CSR 10-6.300 *Conformity of General Federal Actions to State Implementation Plans*, which can be found in Appendix V. This rule sets forth policy, criteria and procedures for demonstrating and assuring conformity to applicable implementation plans.

11.4.4 Source retirement and replacement schedules

40 CFR 51.308(d)(3)(v)(D) requires Missouri to consider source retirement and replacement schedules in developing RPGs. Retirement and replacement will be managed in conformance with existing SIP/TIP requirements pertaining to PSD and New Source Review (NSR).

11.4.5 Smoke Management Plan

40 CFR 51.308(d)(3)(v)(E) requires Missouri to consider smoke management techniques for the purposes of agricultural and forestry management in developing RPGs.

The purpose of the Smoke Management Plan (SMP) adopted by Missouri is to identify the responsibilities of the Missouri Department of Natural Resources, FLMs, and state land managers to coordinate procedures that mitigate the impacts of prescribed fire and wildland fire

used for resource benefits on public health, safety and visibility. This plan is designed to meet the policies of the EPA’s *Interim Air Quality Policy on Wildland and Prescribed Fires* (April 1998) and addresses smoke management through various procedures and requirements in place at various agencies throughout the state.

The department does not intend to submit the SMP for inclusion in the Missouri SIP, but a copy of the Missouri SMP is provided in Appendix X for reference. A letter certifying that the SMP meets the basic requirements will be provided to EPA.

The purpose of a SMP is to mitigate the nuisance and public safety hazards (e.g., on roadways and at airports) posed by smoke intrusions into populated areas; to prevent deterioration of air quality and NAAQS violations; and to address visibility impacts in mandatory federal Class I areas. Some strong indications that an area needs a SMP are: (1) citizens increasingly complain of smoke intrusions; (2) the trend of monitored air quality values is increasing (approaching the daily or annual NAAQS for $PM_{2.5}$ or PM_{10}) because of significant contributions from fires managed for resource benefits; (3) fires cause or significantly contribute to monitored air quality that is already greater than 85 percent of the daily or annual NAAQS for $PM_{2.5}$ or PM_{10}; or (4) fires in the area significantly contribute to visibility impairment in mandatory federal Class I areas. None of these four indicators currently shows a problem in Missouri. However, the Missouri SMP should provide additional protection to the federal Class I areas.

11.4.6 Enforceability of Emission Limitations and Control Measures

40 CFR 51.308(d)(3)(v)(F) requires Missouri to ensure that emission limitations and control measures used to meet RPGs are enforceable.

Missouri has ensured that all emission limitations and control measures used to meet RPGs are enforceable by Missouri law through section 643 of the Revised Statutes of Missouri. In addition, rules developed for CAIR and the NO_X SIP call have placed emission limits on both EGU and non-EGU units. These rules can be found in Appendix V.

11.4.7 Anticipated net effect on visibility resulting from projected changes to emissions

40 CFR 51.308(d)(3)(v)(G) requires Missouri to address the net effect on visibility resulting from changes projected in point, area and mobile source emissions by 2018.

The emission inventory for Missouri projects changes to point, area and mobile source inventories by the end of the first implementation period resulting from population growth; industrial, energy and natural resources development; land management; and air pollution control. A summary of these changes is given in Tables 7.1 and 7.2 for each of the pollutants addressed in the regional haze plan inventory.

The net effect on visibility in Missouri Class I areas resulting from these emission differences is discussed in the CENRAP Technical Support Document (Appendix F).

11.5 FIVE-YEAR REVIEW

For the 2013 five-year review process, Missouri intends to conduct a five factor analysis (four factors plus visibility impact) to address reasonable progress goals set for Mingo and Hercules Glades Class 1 areas.

12.0 COMPREHENSIVE PERIODIC PLAN REVISIONS

40 CFR 51.308(f) requires a state/tribe to revise its regional haze implementation plan and submit a plan revision to EPA by July 31, 2018 and every ten years thereafter. In accordance with the requirements listed in section 51.308(f) of the federal Regional Haze Rule, Missouri commits to revising and submitting this regional haze implementation plan by July 31, 2018 and every ten years thereafter.

The Missouri Department of Natural Resources Air Pollution Control Program is responsible for developing and submitting the required SIP revisions and periodic reports. The plan has been developed and will be maintained in electronic (computer) format as well as in paper copy.

In addition, 40 CFR 51.308(g) requires periodic reports evaluating progress towards the RPGs established for each mandatory Class I area. In accordance with the requirements listed in Section 51.308(g) of the federal rule for regional haze, Missouri commits to submitting a report on reasonable progress to EPA every five years following the initial submittal of the plan. The reasonable progress report will evaluate the progress made towards the RPG for each mandatory Class I area located within Missouri and in each mandatory Class I area located outside Missouri that may be affected by emissions from within Missouri**.** The report will be in the form of a SIP revision.

To establish the criteria in evaluating progress, all requirements listed in 40 CFR 51.308(g) shall be addressed in the plan revision for reasonable progress. These criteria are as follows:

1) Assessment of visibility conditions and changes for each federal Class I area in Missouri;

2) Implementation status of control measures included in plan and a summary of emissions reductions achieved from measures;

3) Analysis of emission reductions by pollutant, identified by source or activity;

4) Assessment of any significant changes in anthropogenic emissions;

5) Assessment of whether current plan is sufficient to meet RPGs; and

6) Review of Missouri's visibility monitoring strategy and any necessary strategy modifications

Figure 12.1 shows a flow chart for 5-year review criteria and actions to be taken if the criteria cannot be met.

All of the required documents (status, summaries, assessments, analysis and reviews will be done by the Missouri Department of Natural Resources Air Pollution Control Program.

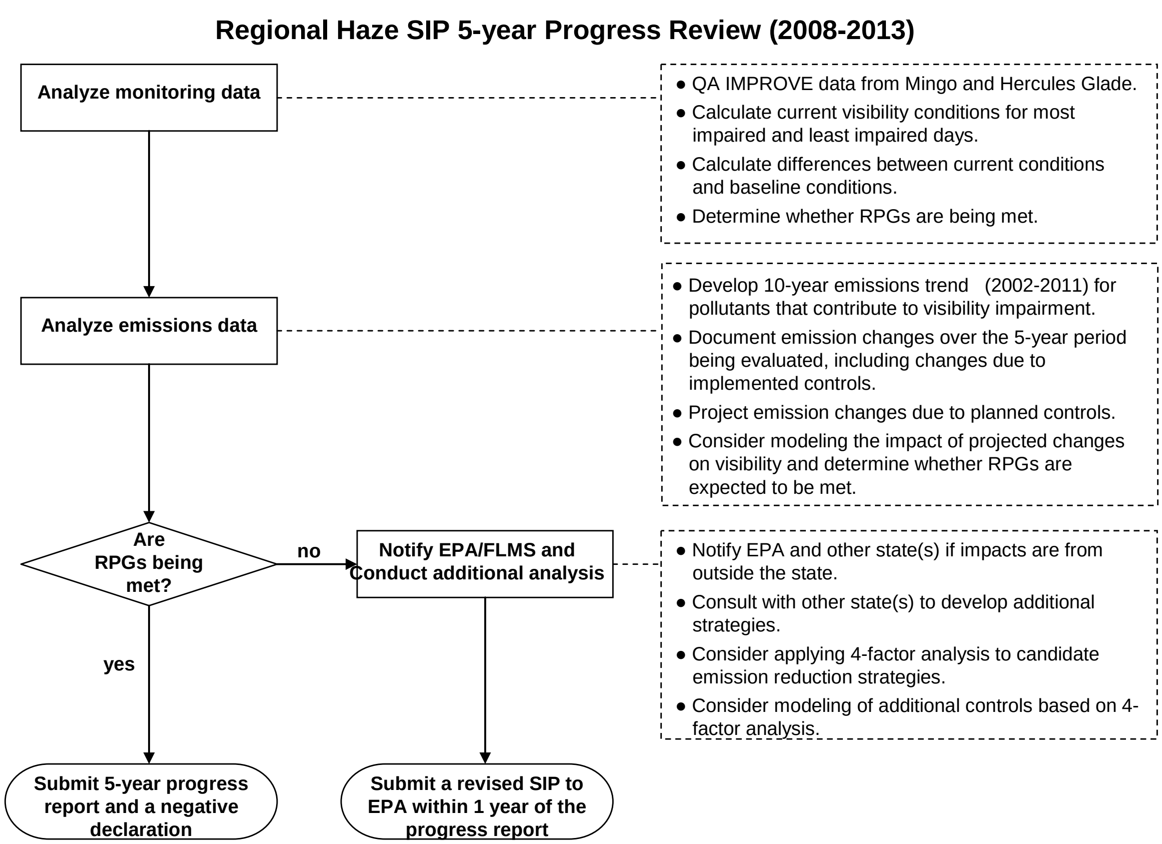

Figure 12.1: 5-Year Progress Review Criteria and Actions

13.0 DETERMINATION OF THE ADEQUACY OF THE EXISTING PLAN

Using the modeling and monitoring as described in this plan, a determination has been made that the plan will continue to meet the goal of showing progress towards reducing visibility. Using the consultation process described in this plan, Missouri's visibility goals have been adequately addressed. In addition, through participation in other states' consultation processes, Missouri's contribution to other states visibility goals is being adequately addressed.

The findings of the five-year progress report as described in Chapter 12.0 will determine which action is appropriate and necessary. Depending on the findings of the five-year progress report, Missouri commits to taking one of the actions listed in 40 CFR 51.308(h):

1) If Missouri determines that the existing plan requires no further substantive revision in order to achieve established goals, the state will provide the EPA with a negative declaration that further revision of the plan is not needed at this time.
2) If Missouri determines that the existing plan may be inadequate to ensure reasonable progress due to emissions from other states that participated in the regional planning process, Missouri will provide notification to the EPA and the other states that participated in regional planning. Missouri will collaborate with the other states through the regional planning process to address the plan's deficiencies.
3) Where Missouri determines that the current plan may be inadequate to ensure reasonable progress due to emissions from another country, the state shall provide notification, along with available information, to the EPA.
4) Where Missouri determines that the existing plan is inadequate to ensure reasonable progress due to emissions within the state, Missouri shall revise its plan to address the plan's deficiencies within one year.

Modeling and monitoring information will be used and the consultation process described in the plan will be followed in carrying out the scheduled incremental administrative and technical actions required in the plan. Any resulting plan revisions could include a revision to goals,

contingency measures, the monitoring strategy, and any other parts of the plan as deemed necessary.

P R O C E E D I N G S

CHAIRMAN PENDERGRASS: The hearing will come to order. Let the record show that Commissioners Jack Baker, Kevin Rosenbohm, Mark Garnett, Gary Pendergrass and Ron Boyer are present.

The Air Conservation Commission of the State of Missouri has called this public hearing pursuant to Section 643.070, Revised Statutes of Missouri, EPA Promulgated Rule 40 CFR 51.102, for the purpose of hearing testimony relating to Missouri Regional Haze Plan and Doe Run Herculaneum Lead Nonattainment Area Plan Revision.

The hearing record will close at 5 p.m., July 2nd, 2009. Anyone who has not been scheduled to appear but who wishes to be heard should indicate that you wish to speak on the sign-in sheets available at the door.

Section 643.100 of the Missouri Statutes provides that all oral testimony be given under oath. Accordingly, when you're called to testify, please present yourself to the court reporter first to be sworn in. When you testify, please state your name, business address and your occupation or affiliation. If you have a prepared statement, it would be helpful if you would provide a copy to the Staff Director, court reporter and members of the Commission.

Mr. Jim Kavanaugh.

MR. GRAF: Good morning, Chairman, members of the Commission. My name is Wayne Graf, and I am employed as the Rules and SIP Unit Chief for the Air Quality Planning Section of the Missouri Department of Natural Resources' Air Pollution Control Program. I work at 1659 East Elm Street in Jefferson City.

I am here to provide testimony on a proposed revision to the Missouri Regional Haze Plan that is summarized beginning on page 95 of the briefing document.

The Missouri Regional Haze Plan was developed to meet the requirements in the U.S. Environmental Protection Agency's Regional Haze Rule. Regional haze consists of very fine particles and gases that impair visibility. In 1977, Congress passed amendments to the Clean Air Act with the goal of improving visibility in Class 1 federal areas. Class 1 areas, as defined by the Clean Air Act, are national parks greater than 6,000 acres, wilderness areas and national memorial parks greater than 5,000 acres and international parks that existed as of 1977.

EPA adopted the Federal Regional Haze Rule on July 1st, 1999. The rule applies to all visibility-impairing pollutants, which includes nitrogen oxides, sulfur dioxides, volatile organic compounds, and

Appendix A

Regional Haze Program Requirements, 40 CFR 51.308

or major modification may have an adverse impact on visibility in any Federal Class I area. Where the State finds that such an analysis does not demonstrate to the satisfaction of the State that an adverse impact will result in the Federal Class I area, the State must, in the notice of public hearing, either explain its decision or give notice as to where the explanation can be obtained.

(b) The plan shall also provide for the review of any new major stationary source or major modification:

(1) That may have an impact on any integral vista of a mandatory Class I Federal area, if it is identified in accordance with § 51.304 by the Federal Land Manager at least 12 months before submission of a complete permit application, except where the Federal Land Manager has provided notice and opportunity for public comment on the integral vista in which case the review must include impacts on any integral vista identified at least 6 months prior to submission of a complete permit application, unless the State determines under § 51.304(d) that the identification was not in accordance with the identification criteria, or

(2) That proposes to locate in an area classified as nonattainment under section 107(d)(1)(A), (B), or (C) of the Clean Air Act that may have an impact on visibility in any mandatory Class I Federal area.

(c) Review of any major stationary source or major modification under paragraph (b) of this section, shall be conducted in accordance with paragraph (a) of this section, and § 51.166(o), (p)(1) through (2), and (q). In conducting such reviews the State must ensure that the source's emissions will be consistent with making reasonable progress toward the national visibility goal referred to in § 51.300(a). The State may take into account the costs of compliance, the time necessary for compliance, the energy and nonair quality environmental impacts of compliance, and the useful life of the source.

(d) The State may require monitoring of visibility in any Federal Class I area near the proposed new stationary source or major modification for such purposes and by such means as the State deems necessary and appropriate.

[45 FR 80089, Dec. 2, 1980, as amended at 64 FR 35765, 35774, July 1, 1999]

§ 51.308 Regional haze program requirements.

(a) *What is the purpose of this section?* This section establishes requirements for implementation plans, plan revisions, and periodic progress reviews to address regional haze.

(b) *When are the first implementation plans due under the regional haze program?* Except as provided in § 51.309(c), each State identified in § 51.300(b)(3) must submit, for the entire State, an implementation plan for regional haze meeting the requirements of paragraphs (d) and (e) of this section no later than December 17, 2007.

(c) [Reserved]

(d) *What are the core requirements for the implementation plan for regional haze?* The State must address regional haze in each mandatory Class I Federal area located within the State and in each mandatory Class I Federal area located outside the State which may be affected by emissions from within the State. To meet the core requirements for regional haze for these areas, the State must submit an implementation plan containing the following plan elements and supporting documentation for all required analyses:

(1) *Reasonable progress goals.* For each mandatory Class I Federal area located within the State, the State must establish goals (expressed in deciviews) that provide for reasonable progress towards achieving natural visibility conditions. The reasonable progress goals must provide for an improvement in visibility for the most impaired days over the period of the implementation plan and ensure no degradation in visibility for the least impaired days over the same period.

(i) In establishing a reasonable progress goal for any mandatory Class I Federal area within the State, the State must:

(A) Consider the costs of compliance, the time necessary for compliance, the energy and non-air quality environmental impacts of compliance, and the remaining useful life of any potentially

affected sources, and include a demonstration showing how these factors were taken into consideration in selecting the goal.

(B) Analyze and determine the rate of progress needed to attain natural visibility conditions by the year 2064. To calculate this rate of progress, the State must compare baseline visibility conditions to natural visibility conditions in the mandatory Federal Class I area and determine the uniform rate of visibility improvement (measured in deciviews) that would need to be maintained during each implementation period in order to attain natural visibility conditions by 2064. In establishing the reasonable progress goal, the State must consider the uniform rate of improvement in visibility and the emission reduction measures needed to achieve it for the period covered by the implementation plan.

(ii) For the period of the implementation plan, if the State establishes a reasonable progress goal that provides for a slower rate of improvement in visibility than the rate that would be needed to attain natural conditions by 2064, the State must demonstrate, based on the factors in paragraph (d)(1)(i)(A) of this section, that the rate of progress for the implementation plan to attain natural conditions by 2064 is not reasonable; and that the progress goal adopted by the State is reasonable. The State must provide to the public for review as part of its implementation plan an assessment of the number of years it would take to attain natural conditions if visibility improvement continues at the rate of progress selected by the State as reasonable.

(iii) In determining whether the State's goal for visibility improvement provides for reasonable progress towards natural visibility conditions, the Administrator will evaluate the demonstrations developed by the State pursuant to paragraphs (d)(1)(i) and (d)(1)(ii) of this section.

(iv) In developing each reasonable progress goal, the State must consult with those States which may reasonably be anticipated to cause or contribute to visibility impairment in the mandatory Class I Federal area. In any situation in which the State cannot agree with another such State or group of States that a goal provides for reasonable progress, the State must describe in its submittal the actions taken to resolve the disagreement. In reviewing the State's implementation plan submittal, the Administrator will take this information into account in determining whether the State's goal for visibility improvement provides for reasonable progress towards natural visibility conditions.

(v) The reasonable progress goals established by the State are not directly enforceable but will be considered by the Administrator in evaluating the adequacy of the measures in the implementation plan to achieve the progress goal adopted by the State.

(vi) The State may not adopt a reasonable progress goal that represents less visibility improvement than is expected to result from implementation of other requirements of the CAA during the applicable planning period.

(2) *Calculations of baseline and natural visibility conditions.* For each mandatory Class I Federal area located within the State, the State must determine the following visibility conditions (expressed in deciviews):

(i) Baseline visibility conditions for the most impaired and least impaired days. The period for establishing baseline visibility conditions is 2000 to 2004. Baseline visibility conditions must be calculated, using available monitoring data, by establishing the average degree of visibility impairment for the most and least impaired days for each calendar year from 2000 to 2004. The baseline visibility conditions are the average of these annual values. For mandatory Class I Federal areas without onsite monitoring data for 2000–2004, the State must establish baseline values using the most representative available monitoring data for 2000–2004, in consultation with the Administrator or his or her designee;

(ii) For an implementation plan that is submitted by 2003, the period for establishing baseline visibility conditions for the period of the first long-term strategy is the most recent 5-year period for which visibility monitoring data are available for the mandatory Class I Federal areas addressed by the plan. For mandatory Class I Federal

areas without onsite monitoring data, the State must establish baseline values using the most representative available monitoring data, in consultation with the Administrator or his or her designee;

(iii) Natural visibility conditions for the most impaired and least impaired days. Natural visibility conditions must be calculated by estimating the degree of visibility impairment existing under natural conditions for the most impaired and least impaired days, based on available monitoring information and appropriate data analysis techniques; and

(iv)(A) For the first implementation plan addressing the requirements of paragraphs (d) and (e) of this section, the number of deciviews by which baseline conditions exceed natural visibility conditions for the most impaired and least impaired days; or

(B) For all future implementation plan revisions, the number of deciviews by which current conditions, as calculated under paragraph (f)(1) of this section, exceed natural visibility conditions for the most impaired and least impaired days.

(3) *Long-term strategy for regional haze*. Each State listed in § 51.300(b)(3) must submit a long-term strategy that addresses regional haze visibility impairment for each mandatory Class I Federal area within the State and for each mandatory Class I Federal area located outside the State which may be affected by emissions from the State. The long-term strategy must include enforceable emissions limitations, compliance schedules, and other measures as necessary to achieve the reasonable progress goals established by States having mandatory Class I Federal areas. In establishing its long-term strategy for regional haze, the State must meet the following requirements:

(i) Where the State has emissions that are reasonably anticipated to contribute to visibility impairment in any mandatory Class I Federal area located in another State or States, the State must consult with the other State(s) in order to develop coordinated emission management strategies. The State must consult with any other State having emissions that are reasonably anticipated to contribute to visibility impairment in any mandatory Class I Federal area within the State.

(ii) Where other States cause or contribute to impairment in a mandatory Class I Federal area, the State must demonstrate that it has included in its implementation plan all measures necessary to obtain its share of the emission reductions needed to meet the progress goal for the area. If the State has participated in a regional planning process, the State must ensure it has included all measures needed to achieve its apportionment of emission reduction obligations agreed upon through that process.

(iii) The State must document the technical basis, including modeling, monitoring and emissions information, on which the State is relying to determine its apportionment of emission reduction obligations necessary for achieving reasonable progress in each mandatory Class I Federal area it affects. The State may meet this requirement by relying on technical analyses developed by the regional planning organization and approved by all State participants. The State must identify the baseline emissions inventory on which its strategies are based. The baseline emissions inventory year is presumed to be the most recent year of the consolidate periodic emissions inventory.

(iv) The State must identify all anthropogenic sources of visibility impairment considered by the State in developing its long-term strategy. The State should consider major and minor stationary sources, mobile sources, and area sources.

(v) The State must consider, at a minimum, the following factors in developing its long-term strategy:

(A) Emission reductions due to ongoing air pollution control programs, including measures to address reasonably attributable visibility impairment;

(B) Measures to mitigate the impacts of construction activities;

(C) Emissions limitations and schedules for compliance to achieve the reasonable progress goal;

(D) Source retirement and replacement schedules;

(E) Smoke management techniques for agricultural and forestry management purposes including plans as currently exist within the State for these purposes;

(F) Enforceability of emissions limitations and control measures; and

(G) The anticipated net effect on visibility due to projected changes in point, area, and mobile source emissions over the period addressed by the long-term strategy.

(4) *Monitoring strategy and other implementation plan requirements.* The State must submit with the implementation plan a monitoring strategy for measuring, characterizing, and reporting of regional haze visibility impairment that is representative of all mandatory Class I Federal areas within the State. This monitoring strategy must be coordinated with the monitoring strategy required in §51.305 for reasonably attributable visibility impairment. Compliance with this requirement may be met through participation in the Interagency Monitoring of Protected Visual Environments network. The implementation plan must also provide for the following:

(i) The establishment of any additional monitoring sites or equipment needed to assess whether reasonable progress goals to address regional haze for all mandatory Class I Federal areas within the State are being achieved.

(ii) Procedures by which monitoring data and other information are used in determining the contribution of emissions from within the State to regional haze visibility impairment at mandatory Class I Federal areas both within and outside the State.

(iii) For a State with no mandatory Class I Federal areas, procedures by which monitoring data and other information are used in determining the contribution of emissions from within the State to regional haze visibility impairment at mandatory Class I Federal areas in other States.

(iv) The implementation plan must provide for the reporting of all visibility monitoring data to the Administrator at least annually for each mandatory Class I Federal area in the State. To the extent possible, the State should report visibility monitoring data electronically.

(v) A statewide inventory of emissions of pollutants that are reasonably anticipated to cause or contribute to visibility impairment in any mandatory Class I Federal area. The inventory must include emissions for a baseline year, emissions for the most recent year for which data are available, and estimates of future projected emissions. The State must also include a commitment to update the inventory periodically.

(vi) Other elements, including reporting, recordkeeping, and other measures, necessary to assess and report on visibility.

(e) *Best Available Retrofit Technology (BART) requirements for regional haze visibility impairment.* The State must submit an implementation plan containing emission limitations representing BART and schedules for compliance with BART for each BART-eligible source that may reasonably be anticipated to cause or contribute to any impairment of visibility in any mandatory Class I Federal area, unless the State demonstrates that an emissions trading program or other alternative will achieve greater reasonable progress toward natural visibility conditions.

(1) To address the requirements for BART, the State must submit an implementation plan containing the following plan elements and include documentation for all required analyses:

(i) A list of all BART-eligible sources within the State.

(ii) A determination of BART for each BART-eligible source in the State that emits any air pollutant which may reasonably be anticipated to cause or contribute to any impairment of visibility in any mandatory Class I Federal area. All such sources are subject to BART.

(A) The determination of BART must be based on an analysis of the best system of continuous emission control technology available and associated emission reductions achievable for each BART-eligible source that is subject to BART within the State. In this analysis, the State must take into consideration the technology available, the costs of compliance, the energy and nonair quality environmental impacts of compliance, any pollution control

equipment in use at the source, the remaining useful life of the source, and the degree of improvement in visibility which may reasonably be anticipated to result from the use of such technology.

(B) The determination of BART for fossil-fuel fired power plants having a total generating capacity greater than 750 megawatts must be made pursuant to the guidelines in appendix Y of this part (Guidelines for BART Determinations Under the Regional Haze Rule).

(C) *Exception.* A State is not required to make a determination of BART for SO_2 or for NO_X if a BART-eligible source has the potential to emit less than 40 tons per year of such pollutant(s), or for PM_{10} if a BART-eligible source emits less than 15 tons per year of such pollutant.

(iii) If the State determines in establishing BART that technological or economic limitations on the applicability of measurement methodology to a particular source would make the imposition of an emission standard infeasible, it may instead prescribe a design, equipment, work practice, or other operational standard, or combination thereof, to require the application of BART. Such standard, to the degree possible, is to set forth the emission reduction to be achieved by implementation of such design, equipment, work practice or operation, and must provide for compliance by means which achieve equivalent results.

(iv) A requirement that each source subject to BART be required to install and operate BART as expeditiously as practicable, but in no event later than 5 years after approval of the implementation plan revision.

(v) A requirement that each source subject to BART maintain the control equipment required by this subpart and establish procedures to ensure such equipment is properly operated and maintained.

(2) A State may opt to implement an emissions trading program or other alternative measure rather than to require sources subject to BART to install, operate, and maintain BART. To do so, the State must demonstrate that this emissions trading program or other alternative measure will achieve greater reasonable progress than would be achieved through the installation and operation of BART. To make this demonstration, the State must submit an implementation plan containing the following plan elements and include documentation for all required analyses:

(i) A demonstration that the emissions trading program or other alternative measure will achieve greater reasonable progress than would have resulted from the installation and operation of BART at all sources subject to BART in the State. This demonstration must be based on the following:

(A) A list of all BART-eligible sources within the State.

(B) An analysis of the best system of continuous emission control technology available and associated emission reductions achievable for each source within the State subject to BART. In this analysis, the State must take into consideration the technology available, the costs of compliance, the energy and nonair quality environmental impacts of compliance, any pollution control equipment in use at the source, and the remaining useful life of the source. The best system of continuous emission control technology and the above factors may be determined on a source category basis. The State may elect to consider both source-specific and category-wide information, as appropriate, in conducting its analysis.

(C) An analysis of the degree of visibility improvement that would be achieved in each mandatory Class I Federal area as a result of the emission reductions achievable from all such sources subject to BART located within the region that contributes to visibility impairment in the Class I area, based on the analysis conducted under paragraph (e)(2)(i)(B) of this section.

(ii) A demonstration that the emissions trading program or alternative measure will apply, at a minimum, to all BART-eligible sources in the State. Those sources having a federally enforceable emission limitation determined by the State and approved by EPA as meeting BART in accordance with § 51.302(c) or paragraph (e)(1) of this section do not need to meet the requirements of the emissions trading program or alternative measure, but may choose to participate if they meet

the requirements of the emissions trading program or alternative measure.

(iii) A requirement that all necessary emission reductions take place during the period of the first long-term strategy for regional haze. To meet this requirement, the State must provide a detailed description of the emissions trading program or other alternative measure, including schedules for implementation, the emission reductions required by the program, all necessary administrative and technical procedures for implementing the program, rules for accounting and monitoring emissions, and procedures for enforcement.

(iv) A demonstration that the emission reductions resulting from the emissions trading program or other alternative measure will be surplus to those reductions resulting from measures adopted to meet requirements of the CAA as of the baseline date of the SIP.

(v) At the State's option, a provision that the emissions trading program or other alternative measure may include a geographic enhancement to the program to address the requirement under § 51.302(c) related to BART for reasonably attributable impairment from the pollutants covered under the emissions trading program or other alternative measure.

(3) A State which opts under 40 CFR 51.308(e)(2) to implement an emissions trading program or other alternative measure rather than to require sources subject to BART to install, operate, and maintain BART may satisfy the final step of the demonstration required by that section as follows: If the distribution of emissions is not substantially different than under BART, and the alternative measure results in greater emission reductions, then the alternative measure may be deemed to achieve greater reasonable progress. If the distribution of emissions is significantly different, the State must conduct dispersion modeling to determine differences in visibility between BART and the trading program for each impacted Class I area, for the worst and best 20 percent of days. The modeling would demonstrate ''greater reasonable progress'' if both of the following two criteria are met:

(i) Visibility does not decline in any Class I area, and

(ii) There is an overall improvement in visibility, determined by comparing the average differences between BART and the alternative over all affected Class I areas.

(4) A State that opts to participate in the Clean Air Interstate Rule cap-and-trade and trade program under part 96 AAA–EEE need not require affected BART-eligible EGU's to install, operate, and maintain BART. A State that chooses this option may also include provisions for a geographic enhancement to the program to address the requirement under § 51.302(c) related to BART for reasonably attributable impairment from the pollutants covered by the CAIR cap-and-trade program.

(5) After a State has met the requirements for BART or implemented emissions trading program or other alternative measure that achieves more reasonable progress than the installation and operation of BART, BART-eligible sources will be subject to the requirements of paragraph (d) of this section in the same manner as other sources.

(6) Any BART-eligible facility subject to the requirement under paragraph (e) of this section to install, operate, and maintain BART may apply to the Administrator for an exemption from that requirement. An application for an exemption will be subject to the requirements of § 51.303(a)(2)–(h).

(f) *Requirements for comprehensive periodic revisions of implementation plans for regional haze.* Each State identified in § 51.300(b)(3) must revise and submit its regional haze implementation plan revision to EPA by July 31, 2018 and every ten years thereafter. In each plan revision, the State must evaluate and reassess all of the elements required in paragraph (d) of this section, taking into account improvements in monitoring data collection and analysis techniques, control technologies, and other relevant factors. In evaluating and reassessing these elements, the State must address the following:

(1) Current visibility conditions for the most impaired and least impaired days, and actual progress made towards natural conditions during the previous implementation period. The period for calculating current visibility

conditions is the most recent five year period preceding the required date of the implementation plan submittal for which data are available. Current visibility conditions must be calculated based on the annual average level of visibility impairment for the most and least impaired days for each of these five years. Current visibility conditions are the average of these annual values.

(2) The effectiveness of the long-term strategy for achieving reasonable progress goals over the prior implementation period(s); and

(3) Affirmation of, or revision to, the reasonable progress goal in accordance with the procedures set forth in paragraph (d)(1) of this section. If the State established a reasonable progress goal for the prior period which provided a slower rate of progress than that needed to attain natural conditions by the year 2064, the State must evaluate and determine the reasonableness, based on the factors in paragraph (d)(1)(i)(A) of this section, of additional measures that could be adopted to achieve the degree of visibility improvement projected by the analysis contained in the first implementation plan described in paragraph (d)(1)(i)(B) of this section.

(g) *Requirements for periodic reports describing progress towards the reasonable progress goals.* Each State identified in § 51.300(b)(3) must submit a report to the Administrator every 5 years evaluating progress towards the reasonable progress goal for each mandatory Class I Federal area located within the State and in each mandatory Class I Federal area located outside the State which may be affected by emissions from within the State. The first progress report is due 5 years from submittal of the initial implementation plan addressing paragraphs (d) and (e) of this section. The progress reports must be in the form of implementation plan revisions that comply with the procedural requirements of § 51.102 and § 51.103. Periodic progress reports must contain at a minimum the following elements:

(1) A description of the status of implementation of all measures included in the implementation plan for achieving reasonable progress goals for mandatory Class I Federal areas both within and outside the State.

(2) A summary of the emissions reductions achieved throughout the State through implementation of the measures described in paragraph (g)(1) of this section.

(3) For each mandatory Class I Federal area within the State, the State must assess the following visibility conditions and changes, with values for most impaired and least impaired days expressed in terms of 5-year averages of these annual values.

(i) The current visibility conditions for the most impaired and least impaired days;

(ii) The difference between current visibility conditions for the most impaired and least impaired days and baseline visibility conditions;

(iii) The change in visibility impairment for the most impaired and least impaired days over the past 5 years;

(4) An analysis tracking the change over the past 5 years in emissions of pollutants contributing to visibility impairment from all sources and activities within the State. Emissions changes should be identified by type of source or activity. The analysis must be based on the most recent updated emissions inventory, with estimates projected forward as necessary and appropriate, to account for emissions changes during the applicable 5-year period.

(5) An assessment of any significant changes in anthropogenic emissions within or outside the State that have occurred over the past 5 years that have limited or impeded progress in reducing pollutant emissions and improving visibility.

(6) An assessment of whether the current implementation plan elements and strategies are sufficient to enable the State, or other States with mandatory Federal Class I areas affected by emissions from the State, to meet all established reasonable progress goals.

(7) A review of the State's visibility monitoring strategy and any modifications to the strategy as necessary.

(h) *Determination of the adequacy of existing implementation plan.* At the same time the State is required to submit any 5-year progress report to EPA in accordance with paragraph (g) of this section, the State must also take one of the following actions based upon

the information presented in the progress report:

(1) If the State determines that the existing implementation plan requires no further substantive revision at this time in order to achieve established goals for visibility improvement and emissions reductions, the State must provide to the Administrator a negative declaration that further revision of the existing implementation plan is not needed at this time.

(2) If the State determines that the implementation plan is or may be inadequate to ensure reasonable progress due to emissions from sources in another State(s) which participated in a regional planning process, the State must provide notification to the Administrator and to the other State(s) which participated in the regional planning process with the States. The State must also collaborate with the other State(s) through the regional planning process for the purpose of developing additional strategies to address the plan's deficiencies.

(3) Where the State determines that the implementation plan is or may be inadequate to ensure reasonable progress due to emissions from sources in another country, the State shall provide notification, along with available information, to the Administrator.

(4) Where the State determines that the implementation plan is or may be inadequate to ensure reasonable progress due to emissions from sources within the State, the State shall revise its implementation plan to address the plan's deficiencies within one year.

(i) *What are the requirements for State and Federal Land Manager coordination?* (1) By November 29, 1999, the State must identify in writing to the Federal Land Managers the title of the official to which the Federal Land Manager of any mandatory Class I Federal area can submit any recommendations on the implementation of this subpart including, but not limited to:

(i) Identification of impairment of visibility in any mandatory Class I Federal area(s); and

(ii) Identification of elements for inclusion in the visibility monitoring strategy required by § 51.305 and this section.

(2) The State must provide the Federal Land Manager with an opportunity for consultation, in person and at least 60 days prior to holding any public hearing on an implementation plan (or plan revision) for regional haze required by this subpart. This consultation must include the opportunity for the affected Federal Land Managers to discuss their:

(i) Assessment of impairment of visibility in any mandatory Class I Federal area; and

(ii) Recommendations on the development of the reasonable progress goal and on the development and implementation of strategies to address visibility impairment.

(3) In developing any implementation plan (or plan revision), the State must include a description of how it addressed any comments provided by the Federal Land Managers.

(4) The plan (or plan revision) must provide procedures for continuing consultation between the State and Federal Land Manager on the implementation of the visibility protection program required by this subpart, including development and review of implementation plan revisions and 5-year progress reports, and on the implementation of other programs having the potential to contribute to impairment of visibility in mandatory Class I Federal areas.

[64 FR 35765, July 1, 1999, as amended at 70 FR 39156, July 6, 2005]

§ 51.309 Requirements related to the Grand Canyon Visibility Transport Commission.

(a) *What is the purpose of this section?* This section establishes the requirements for the first regional haze implementation plan to address regional haze visibility impairment in the 16 Class I areas covered by the Grand Canyon Visibility Transport Commission Report. For the years 2003 to 2018, certain States (defined in paragraph (b) of this section as Transport Region States) may choose to implement the Commission's recommendations within the framework of the national regional haze program and applicable requirements of the Act by complying with the provisions of this section, as supplemented by an approvable Annex to

MISSOURI AIR CONSERVATION COMMISSION
WILL HOLD PUBLIC HEARING

JEFFERSON CITY, MO – The Missouri Air Conservation Commission will hold a public hearing on Missouri State Implementation Plan--Missouri Regional Haze Plan on Thursday, December 6, 2007. The Public Hearing will begin at 9 a.m. at the Harry S. Truman Building, Room 400, 301 W. High Street, Jefferson City, MO. The commission will hear testimony related to the following item(s).

* Missouri State Implementation Plan--Missouri Regional Haze Plan

On July 1, 1999, the U.S. Environmental Protection Agency (EPA) adopted the federal Regional Haze Rule with federal visibility requirements. Missouri has two federal Class I areas within its borders. The Missouri Regional Haze Plan was developed to meet the requirements of EPA's Regional Haze Rule and includes a description of the consultation process used to develop the plan, reasonable progress goals for achieving natural visibility conditions, calculations of baseline and natural visibility conditions, long-term strategy for regional haze, monitoring strategy and other implementation plan requirements.

Documents for the above item(s) will be available for review at the Missouri Department of Natural Resources, Air Pollution Control Program, 1659 Elm Street, Jefferson City, (573) 751-4817 and in the Public Notices section of the program web site www.dnr.mo.gov/env/apcp/index.html.

Persons with disabilities requiring special services or accommodations to attend the meeting can make arrangements by calling the department directly at (573) 526-4679, the department's toll free number at (800) 334-6946, or by writing two weeks in advance of the meeting to: Missouri Department of Natural Resources, Air Conservation Commission Secretary, P.O. Box 176, Jefferson City, MO 65102. Hearing impaired persons may contact the program through Relay Missouri, (800) 735-2966.

The commission holds public hearings under the provisions of chapter 643, RSMo. Citizens wishing to speak at the public hearing should notify the secretary to the Missouri Air Conservation Commission, Missouri Department of Natural Resources, Air Pollution Control Program, P.O. Box 176, Jefferson City, Missouri 65102-0176, or telephone (573) 526-4679. The department requests persons intending to give verbal presentations also provide a written copy of their testimony to the commission secretary at the time of the public hearing. The department also will accept written or email comments for the record until 5 p.m. on December 13, 2007; please send two copies of written comments to Chief, Operations Section, Air Pollution Control Program, P.O. Box 176, Jefferson City, MO 65102-0176. Email comments regarding rule actions shall be sent to apcprulespn@dnr.mo.gov and email comments regarding plan actions shall be sent to apcpsppn@dnr.mo.gov. All written and email comments and public hearing testimony will be equally considered.

Public hearing items may be adopted by the Missouri Air Conservation Commission as provided for under authority of 643.050, RSMo. For more information or a complete meeting agenda, including items being presented for adoption, contact the Missouri Department of Natural Resources' Air Pollution Control Program at (573) 751-4817.

Notary Public, BARBARA KLIETHERMES Notary Public - State of Missouri My Commission Expires March 13, 2013 Cole County Commission #09529328

My term as Notary Public expires ______

MISSOURI AIR CONSERVATION COMMISSION WILL HOLD PUBLIC HEARING

JEFFERSON CITY, MO -- The Missouri Air Conservation Commission will hold a public hearing on the Missouri State Implementation Plan regarding the Regional Haze Plan and the Doe Run Herculaneum Lead Nonattainment Area Plan on Thursday, June 25, 2009. The Public Hearing will begin at 9 a.m. at the Elm Street Conference Center, 1730 East Elm Street, Lower Level, Bennett Springs Conference Room, Jefferson City, Missouri. The commission will hear testimony related to the following item(s).

* Missouri State Implementation Plan--Missouri Regional Haze Plan
The Missouri Regional Haze Plan was developed to meet the requirements of the federal Regional Haze Rule. The Missouri Regional Haze Plan is being revised as result of the Holcim, Inc. Clarksville kiln Best Available Retrofit Technology (BART) findings and the U.S. Court of Appeal's late December 2008 decision on the Clean Air Interstate Rule. The department finalized a BART agreement with Holcim to address air quality issues related to visibility impacts at nearby Class I areas. At the same time, clarifications have been made to the content of the plan as a result of inquiries made by the U.S. Environmental Protection Agency during review of this plan for inclusion in the Missouri State Implementation Plan.

* Missouri State Implementation Plan - Doe Run Herculaneum Lead Nonattainment Area
This proposed amendment to the 2007 Revision to the State Implementation Plan (SIP) for the Herculaneum Lead Nonattainment Area will establish the enforceable building ventilation system limits for the Building Ventilation and Particle Capture project. Minimum fan amperages and flow rate limits at the Doe Run Company's Herculaneum Primary Lead Smelter are used to meet the requirements of the 2007 Consent Judgment. These limits are based upon the results of a building ventilation study completed by Doe Run and, once adopted, will become enforceable as an amendment to the 2007 Consent Judgement. Also as a result of this study, the Doe Run Herculaneum Work Practices Manual is being amended with the test methods, implementation and compliance provisions related to these limits. For the purposes of continual improvement, the Work Practices Manual is also being updated to restrict construction projects during periods of low temperature that would prohibit the use of water for dust suppression.

Documents for the above item(s) will be available for review at the Missouri Department of Natural Resources, Air Pollution Control Program, 1659 Elm Street, Jefferson City, (573) 751-4817 and in the Public Notices section of the program web site www.dnr.mo.gov/env/apcp/index.html. This information will be available at least 30 days prior to the public hearing date.

Persons with disabilities requiring special services or accommodations to attend the meeting can make

Comments and Responses to the Missouri Regional Haze Plan

AND

Comments and Responses to the 2009 Revision to the Missouri Regional Haze Plan

COMMENTS AND RESPONSES ON

PROPOSED MISSOURI STATE IMPLEMENTATION PLAN– STATE OF MISSOURI REGIONAL HAZE PLAN

AND

RECOMMENDATION FOR ADOPTION

On December 6, 2007, the Missouri Air Conservation Commission held a public hearing concerning the proposed revision to the Missouri State Implementation Plan for inclusion of a State of Missouri Regional Haze Plan. The following is a summary of comments received and the Missouri Department of Natural Resources' corresponding responses. Any changes to the proposed regional haze plan are identified in the responses to the comments.

The Missouri Department of Natural Resources' Air Pollution Control Program recommends the commission adopt the plan as revised. If the commission adopts this plan action, it will be the department's intention to submit this new plan to the U.S. Environmental Protection Agency to replace the current visibility plan in the Missouri State Implementation Plan.

SUMMARY OF COMMENTS: The department's Air Pollution Control Program received comments from five (5) sources: the Mississippi Lime Company, a private citizen, the U.S. Department of Interior Fish and Wildlife Service (FWS), the U.S. Environmental Protection Agency (EPA), and the U.S. Department of Agriculture Forest Service (FS).

COMMENT #1: The Mississippi Lime Company commented that one of their two units that were removed from Best Available Retrofit Technology (BART) consideration due to a permit condition requiring shutdown, has become a BART-eligible emission unit as a result of their request to remove that condition from the permit for that unit. As a BART-eligible unit, it is subject to BART screening evaluation. This evaluation has been conducted and the results show that this unit along with the company's other two current BART-eligible emission units remain below the 0.5 deciview impact level and, therefore, remain exempt from BART.
RESPONSE AND EXPLANATION OF CHANGE: The language in the BART chapter of the plan has been revised to reflect that Mississippi Lime Company has three BART-eligible units that do not need to install BART controls to meet the federal Regional Haze Rule requirements.

COMMENT #2: A private citizen commented that the regional haze plan does not appear to monitor or address nighttime visibility concerns, particularly with regard to man-made light emissions. The comment requests justification for how the plan will achieve the natural visibility controls of the Clean Air Act without a plan to reduce nighttime light emissions.
RESPONSE: The EPA's Regional Haze Rule does not regulate light emissions directly. The goals of the rule, as shown in the regional haze plan, can be met without requiring reductions in nighttime emissions. However, the improved visibility levels that will result from regional haze plans will help improve nighttime visibility. No changes were made to the plan as a result of this comment.

COMMENT #3: The FWS commented that that it was their understanding that the comments submitted by the U.S. Department of Interior in October 2007 on the draft Missouri Regional

Haze Plan were not considered to be “on the public record” because they were provided prior to the official public comment period. Therefore, the FWS resubmitted their comments into the official rulemaking process by attachment to a December 2007 letter.
RESPONSE AND EXPLANATION OF CHANGE: The official “rulemaking” process does not typically include early draft rule text comments in the formal comments and responses on proposed rule actions because these early comments are taken into account in the proposed rulemaking that is presented at public hearing. However, extra effort was made to share early draft plan comments as a result of this comment. The public hearing presentation made before the Missouri Air Conservation Commission and the public included discussion on the regional haze plan consultation process. This discussion mentioned that the consultation process included the Federal Land Managers and that they provided comments on the draft plan. The summary of comments and responses includes comments received during the consultation process and on the proposed plan that was presented at public hearing.

COMMENT #4: The FWS and the FS commented that their review of the draft Missouri Regional Haze Plan indicated a need to more completely address the land management agency priorities which include the following areas of interest: baseline, natural condition and uniform rate, emission inventories, area of influence, reasonable progress goals and long-term strategy, fire, regional consistency, verification and contingencies and coordination and consultation.
RESPONSE AND EXPLANATION OF CHANGE: This comment on the early draft plan resulted in additional language being added to the proposed plan that was presented at public hearing to more completely address the land management agency priorities and additional revisions have been made to the plan as a result of comments received during the public comment period.

COMMENT #5: The FWS commented that the draft Missouri Regional Haze Plan relied on a pattern of referencing technical documents that did not include explanations of the State’s reasoning on deriving conclusions. They also requested that the discussion in the draft plan be expanded regarding how important federal rule elements were approached and evaluated.
RESPONSE AND EXPLANATION OF CHANGE: This comment on the early draft plan was considered and additional explanatory language was added to the proposed plan that was presented at public hearing to describe the State’s approach, evaluation and reasoning on deriving conclusions. In addition, revisions have been made to the plan as a result of comments received during the public comment period.

COMMENT #6: The FWS commented that discussions of specific plan elements are re-visited in several sections, often with contradictory or incorrect information. More robust explanations of specific topic areas are often included in non-related chapters.
RESPONSE AND EXPLANATION OF CHANGE: Early in the development of the regional haze plan, it was decided to structure the Missouri Regional Haze Plan as closely as possible to the plan template provided by the Central Regional Air Planning Association (CENRAP). The reasoning was that if all states were to structure their plans to align to this template, then the review of plans would be much easier for the Federal Land Managers. Since it is not our intent to have contradictory or incorrect information in the plan, the plan was reviewed for accuracy at the same time that more robust explanations were added with the reasoning for the conclusions being drawn in the plan. At the same time, information in each chapter of the document was

reviewed to determine if it was in an appropriate section of the document while keeping with the template structure.

COMMENT #7: The FWS requested that the baseline and natural condition values being used as a basis for the draft Missouri Regional Haze Plan be reviewed for consistency with the latest available information. They also asked that the plan state if the estimates were generated using the old or the new Interagency Monitoring of PROtected Visual Environments (IMPROVE) equation.
RESPONSE AND EXPLANATION OF CHANGE: As a result of this comment, IMPROVE information in the early draft plan was reviewed for consistency with the latest available information. Additional language was also added to the proposed plan that was presented at public hearing explaining that the plan is based on the new IMPROVE equation.

COMMENT #8: The FWS commented that the department should consider providing additional information in the draft Missouri Regional Haze Plan. They suggest a summary of the IMPROVE equations and the calculations necessary to evaluate baseline conditions and providing a specific description in an appendix. Also, it was noted that the plan references an "ftp" website that is not publicly available.
RESPONSE AND EXPLANATION OF CHANGE: As a result of this comment, Appendix G has been added to the plan to provide a more detailed explanation of the revised IMPROVE equation. Therefore, the website reference was no longer necessary and has been removed from the plan text.

COMMENT #9: The FWS commented that the department should identify whether the "Uniform Rate of Reasonable Progress Glide Paths" in section 8.4 of the draft Missouri Regional Haze Plan were produced using actual model output or the results of applying a relative reduction factor. Also, the concept of "Method 1" is mentioned in the Uniform Rate of Progress graphs and should be explained in the plan.
RESPONSE AND EXPLANATION OF CHANGE: Section 8.4 of the plan indicates that the uniform rate of reasonable progress glide paths were produced by drawing a line from the baseline observed visibility conditions for the 20 percent worst days to natural visibility conditions in 2064. Neither model output nor relative reduction factors were used in the construction of the glide paths. Therefore, no changes were made to the plan regarding how uniform rate of reasonable progress glide paths were produced. However, language was added to section 8.4 clarifying the procedures used in the CENRAP 2018 modeled visibility projections, which are labeled "Method 1" in the uniform rate of progress graphs in the plan. The "Method 1" procedures conform to the EPA's default method of calculating future-year visibility conditions.

COMMENT #10: The FWS commented that statements in section 6.4, referencing ambient ammonia monitoring in CENRAP regions and indicating that high concentrations of ammonia are occurring with a considerable regularity, are in conflict with section 9.2 that stated ammonia was being discarded from consideration due to the inventory being "very uncertain" regarding anthropogenic contribution. The FWS requests the plan discuss whether the observations apply in Missouri, whether the department has investigated winter dates when 20% worst visibility occurs and how ammonia emissions were considered in evaluating the reasonable progress goal. The FWS is concerned that the department should re-evaluate ammonia emission effects on

visibility at the Mingo Wilderness Area, considering the high nature of measurements that have potentially occurred.
RESPONSE: The CENRAP/Midwest Regional Planning Organization (RPO) special ammonia sampling was conducted in the upper Midwest, including central Missouri, where agricultural sources of ammonia are numerous. The sampling was conducted primarily to aid in understanding the association of free ammonia with regional haze pollutants, but was not able to directly relate ammonia sources to haze. While that seems to be a given, the BART discussion in section 9.2 points out that not only is the overall ammonia inventory, including agricultural, very limited nationally, but that the BART eligible sources were not large ammonia emitters, so that pollutant was not considered in the BART evaluation. Ammonia was part of the modeling analysis for the 20% worst days, and is discussed in the CENRAP Modeling Technical Support Document used as a basis for reasonable progress growth evaluation. Currently, the EPA is conducting a study with large concentrated animal feeding operations to determine improved emission factors. Contingent on the outcome of the mid-course review discussed in section 13, an evaluation of ammonia controls may be included in the four (five) factor analysis, which could include these new emission factors. No changes were made to the plan as a result of this comment.

COMMENT #11: The FWS commented that the department should consider combining the draft Missouri Regional Haze Plan discussions on emission inventories into one chapter.
RESPONSE: Early in the development of the regional haze plan, it was decided to structure the Missouri Regional Haze Plan as closely as possible to the plan template provided by the CENRAP. The reasoning was that if all states were to structure their plans to align to this template, then the review of plans would be much easier for the Federal Land Managers. Therefore, no changes were made to the plan as a result of this comment.

COMMENT #12: The FWS and EPA commented that the draft Missouri Regional Haze Plan needs to commit to periodically updating the future emission inventory projections used for regional haze decision making.
RESPONSE AND EXPLANATION OF CHANGE: As a result of this comment, section 7.3 was added to the plan with language that commits to periodic reviews and updates of base year inventories and future-year emissions projections.

COMMENT #13: The FWS commented that the BART chapter discussion of the draft Missouri Regional Haze Plan regarding the Doe Run-Glover facility should explicitly address the potential scenario that Doe Run-Glover might resume operation under their valid air quality permit.
RESPONSE AND EXPLANATION OF CHANGE: This comment on the early draft plan resulted in additional language being added to section 9.2 of the proposed plan that was presented at public hearing to further address address Doe Run-Glover possibly resuming operation under their valid air quality permit. To supplement this comment and on-going operating permit issues, the department has sent a letter to Doe Run-Glover requesting clarification of Doe Run’s plans. This letter clarified the intent of the department to require a BART analysis for the facility if operations of the large units commenced. The letter is included in Appendix J. At this time, the department does not believe the source will commence operation and does not intend to pursue a BART evaluation unless contrary information is presented.

COMMENT #14: The FWS requested that the reasons for excluding volatile organic compounds (VOCs) and ammonia from BART determinations should be expanded in the draft Missouri Regional Haze Plan.
RESPONSE AND EXPLANATION OF CHANGE: As a result of this comment, language was added to the proposed plan that was presented at public hearing expanding on the reasoning for excluding VOCs and ammonia from BART determinations.

COMMENT #15: The FWS requested that the text in the draft Missouri Regional Haze Plan specify whether the CALPUFF/CALPOST screening analyses followed the CENRAP screening modeling protocol, and if not, the reasons for not following that protocol.
RESPONSE: The CALPUFF/CALPOST screening analyses conducted do not explicitly follow the CENRAP protocol for this evaluation because the department evaluated CALPOST Method2 and Method6. This level of review is beyond the CENRAP protocol and ensures that sources were screened using a more conservative approach than specified in the CENRAP protocol. No changes were made to the plan as a result of this comment.

COMMENT #16: The FWS commented that the draft Missouri Regional Haze Plan approach that uses the 98th percentile test on modeling results to determine BART eligible source impacts is not appropriate according to CENRAP screening modeling protocol. In is unclear whether the department refined the meterorology processing done in the modeling in order to move to refined modeling which would then allow for use of the 98th percentile approach. Also, when using the 98th percentile approach, the eigth-highest daily visibility impact predicted in a modeling year should be used rather than the seventh-highest value.
RESPONSE AND EXPLANATION OF CHANGE: The first portion of this comment on the early draft plan resulted in language being included in the proposed plan that was presented at public hearing to include information specific to the use of “refined” meteorology and the 98th percentile visibility change. As a result of the second part of the comment regarding the use of the 8th highest daily visibility impact, supplemental changes have been made to the plan to reflect that the 98th percentile values represent the 8th highest visibility impact instead of the the 7th highest visibility impact.

COMMENT #17: The FWS requested that the BART chapter of the draft Missouri Regional Haze Plan include information regarding Noranda Aluminum and the University of Missouri-Columbia, including any modeling protocols for the refined analyses, modeling results and BART engineering determinations as they become available.
RESPONSE AND EXPLANATION OF CHANGE: The information requested by this comment was included in the proposed plan that was presented at public hearing.

COMMENT #18: The FWS commented that there are inconsistent statements in the draft Missouri Regional Haze Plan about the BART decisions pertaining to electric generating units (EGUs) that are also subject to the Clean Air Interstate Rule (CAIR). They requested that additional information be provided explaining how CAIR EGU sources were evaluated for primary particulate matter and primary sulfate emissions.
RESPONSE AND EXPLANATION OF CHANGE: As a result of this comment, the BART chapter in the proposed plan that was presented at public hearing was amended to remove

inconsistencies and additional information was included explaining the evaluation of EGUs including the determination of primary particulate matter emissions.

COMMENT #19: The FWS recommended that the tables in Appendices G and I of the draft Missouri Regional Haze Plan be reformatted for ease in reading this information.
RESPONSE AND EXPLANATION OF CHANGE: The tables in these appendices have been reformatted in the proposed plan that was presented at public hearing.

COMMENT #20: The FWS commented that the consultation plan in Appendix F of the draft Missouri Regional Haze Plan contains several Area of Influence (AOI) maps for the affected Class I areas in and near Missouri. These maps should be integral to the discussions in the plan. The information in section 11.5 of the draft Missouri Regional Haze Plan references tables in the emissions inventory section that only presents a summary of 2002 and 2018 emissions inventory for just Missouri sources and only in aggregrate by source category. Also, section 11.5 does not provide any of the CENRAP graphics for Class I areas of concern. The plan needs to discuss attribution of haze-causing pollution and the results of consultations with neighboring states regarding achieving Reasonable Progress Goals for the Missouri Class I areas.
RESPONSE AND EXPLANATION OF CHANGE: As a result of this comment and FS comments on the early draft plan, discussion language in the proposed plan that was presented at public hearing was expanded to include AOI maps, applicable CENRAP graphics, additional emissions allocation information and attribution of haze-causing pollution that includes results of consultations with neighboring states.

COMMENT #21: The FWS and the FS commented that Chapter 10 of the draft Missouri Regional Haze Plan establishes that 2018 reasonable progress goals are equal to the 2018 year value of the uniform rate of progress graph. This is not consistent with the federal Regional Haze Rule. However, the 2018 visibility projections presented in section 8.4 were based on emission growth and on-the-books controls that will be implemented between 2002 and 2018. Based on this information, the federal Regional Haze Rule requires Missouri to adopt the results of the visibility projection as its 2018 Reasonable Progress Goal.
RESPONSE AND EXPLANATION OF CHANGE: As a result of FWS and FS comments on the early draft plan, discussion language in the proposed plan that was presented at public hearing was revised to show that the 2018 visibility projections based on emissions growth and on-the books controls are the reasonable progress goals.

COMMENT #22: The FWS and the FS commented that Chapter 10 of the draft Missouri Regional Haze Plan does not address the reasonable progress goals for the best 20% visibility days as required by the federal Regional Haze Rule.
RESPONSE AND EXPLANATION OF CHANGE: As a result of this comment, the discussions in the proposed plan that was presented at public hearing were expanded to address the best 20% visibility days.

COMMENT #23: The FWS commented that the discussion in Chapter 10 of the draft Missouri Regional Haze Plan does not include the required four-factor analysis for establishing Reasonable Progress Goals. The plan only applies the four-factor analysis to the CAIR-affected and BART-affected sources within Missouri. The plan does not include the required four-factor

analysis for non-EGUs in establishing the Reasonable Progress Goals. This is a misinterpretation of the EPA guidance that states that the four-factor analysis doesn't need to "reassess the reasonable progress factors for sources subject to BART for which you have already completed a BART analysis."

RESPONSE: The glide slope approach required in the 1999 federal Regional Haze Rule was applied in establishing the reasonable progress goals for each Class I area. The draft regional haze guidance published in 2006 radically departs from the federal Regional Haze Rule. The guidance declares that the States should conduct reviews (4-factor analysis) for all stationary sources to identify any potential controls before determining the reasonable progress goal. The reasonable progress goal selection process in the guidance is fundamentally inconsistent with the glide slope analytical approach contained in the federal Regional Haze Rule. It also contradicts the traditional approach used in state implementation plans for nonattainment areas.

If modeling failed to achieve the Uniform Rate of Progress goals for Missouri Class I areas, then conducting a 4-factor analysis would be appropriate for non-EGUs. However, visibility projections based on CENRAP modeling indicate that Missouri will be able to meet the Uniform Rate of Progress goals for both Mingo and Hercules Glades Class I areas in 2018. Missouri has not selected a strategy to achieve greater reductions than necessary to meet the Uniform Rate of Progress goals because the state must follow state statute 643.055 that does not allow standards stricter than those required under the provisions of the federal Clean Air Act. No changes were made to the plan as a result of this comment.

COMMENT #24: The FWS commented that section 11.4 of the draft Missouri Regional Haze Plan inaccurately refers to the regional haze process as an attainment demonstration. However, it provides the framework for each State to establish those Reasonable Progress Goals based upon the statutory four-factor analysis.

RESPONSE: The glide slope approach required in the 1999 federal Regional Haze Rule was applied in establishing the reasonable progress goals for each Class I area as described in the response to COMMENT #23. Therefore, no changes were made to the plan as a result of this comment.

COMMENT #25: The FWS, the FS and EPA requested that the discussion in section 11.6.4 of the draft Missouri Regional Haze Plan be expanded to elaborate on how the Prevention of Significant Deterioration (PSD) and New Source Review (NSR) permitting programs will be utilized as part of the long term strategy for meeting Reasonable Progress Goals. EPA stated that, along with explaining to what extent the State relied on the PSD and NSR programs in developing the long-term strategy, the State should provide more explanation in the plan on how these programs satisfy the State's obligation to consider construction activity, and source retirement and replacement schedules.

RESPONSE AND EXPLANATION OF CHANGE: As a result of this comment, the discussions in the proposed plan that was presented at public hearing were expanded to elaborate on how the PSD and NSR permitting programs will be used in the long term strategy. The department still plans to coordinate the visbility review of major new source review permits with the Federal Land Manager for applicable Class I areas. The requirements of the Clean Air Act with respect to this type of coordination will still be met. In addition, the continued application of nonattainment permitting and the PSD program in Missouri will help ensure that facilities are in

compliance with all standards including the National Ambient Air Quality and PSD increment standards in Missouri. The existing permitting program to ensure compliance with the applicable standards remains sufficient to meet the obligation to consider construction activities in Missouri along with the continued coordination with EPA and the land managers.

COMMENT #26: The FWS commented that the draft Missouri Regional Haze Plan should describe how natural and non-natural smoke emissions from wild and prescribed fires currently affect the Class I areas and how these effects may change during the planning period.
RESPONSE AND EXPLANATION OF CHANGE: Fire, while not considered to be a main source of visibility impairment in any Class I area, is one source of regional haze. Minimizing the adverse effects of smoke results from a concerted effort to utilize prescribed fires in a beneficial manner consistent with proven management strategies. These strategies include understanding and using meteorological conditions when scheduling burning to avoid sending smoke into a sensitive area, controlling the rate of emissions to promote dilution and dispersion, and minimizing smoke output per unit area through emissions reduction techniques. Currently, fires do not significantly contribute to visibility impairment in Class I Federal areas located in Missouri and the affects of wild and prescribed fires are not expected to change over the planning period of this plan. However, language was added to the plan to describe how adverse affects of smoke from wild and prescribed fires are minimized.

COMMENT #27: The FWS commented that the draft Missouri Regional Haze Plan and the Missouri Smoke Management Plan should identify Mingo as a smoke sensitive area and prescribed burners should be required to apply the appropriate smoke management techniques to minimize smoke impacts.
RESPONSE: Both the Mingo National Wildlife Area and the Hercules Glades Wilderness Area are identified as federal Class I Areas and, as such, are considered smoke sensitive. The implementation of the Missouri Smoke Management Plan encourages prescribed burners to use best smoke management practicies to minimize smoke impacts. No changes were made to the plan as a result of this comment.

COMMENT #28: The FWS commented that the draft Missouri Regional Haze Plan should refer to the Missouri Smoke Management Plan in a way that does not require plan updates each time the Smoke Management Plan is updated. They also request that Missouri indicate whether Missouri intends to certify the Smoke Management Plan as provided for by the 1998 EPA Interim Air Quality Policy on Wildland and Prescribed Fire.
RESPONSE AND EXPLANATION OF CHANGE: The Missouri Regional Haze Plan that was presented at public hearing refers to the Missouri Smoke Management Plan in a way that does not require plan updates each time the Smoke Management Plan is updated. A copy of the Missouri Smoke Management Plan is provided as an appendix to the plan for reference. Missouri does intend for the Missouri Smoke Management Plan to be certified as provided for by the 1998 EPA Interim Air Quality Policy on Wildland and Prescribed Fire. A letter certifying that the smoke management plan meets the basic requirements is being provided to EPA.

COMMENT #29: The FWS commented that neither section 11.6.5 of the draft Missouri Regional Haze Plan nor the Missouri Smoke Management Plan addresses ongoing development, review and updating of the plan as a result of coordination and consultation during the

development of future progress reports and plan revisions. Also, they do not provide for federal land manager agency involvement.
RESPONSE AND EXPLANATION OF CHANGE: This comment on the early draft plan resulted in additional language being added in Section 11.4.5 of the proposed plan that was presented at public hearing to clarify that the department does not intend to submit the smoke management plan for inclusion in the Missouri SIP. The additional plan language states that a copy of the Missouri Smoke Management Plan is included in the appendix of the regional haze plan for reference and a letter certifying that the smoke management plan meets the basic requirements will be provided to EPA. This allows changes to be made to the smoke management plan without undergoing a SIP revision. The language in Section 11.2 of the proposed plan that was presented at public hearing addresses the coordination and consultation during the development of future progress reports and plan revisions.

COMMENT #30: The FWS commented that there are three RPOs that also cover the Mingo Wilderness Area. Missouri should consider including language in the draft Missouri Regional Haze Plan to highlight the importance of the ongoing verification and contingency provisions in view of the varying and different results of the three RPOs.
RESPONSE AND EXPLANATION OF CHANGE: As a result of this comment, a new section 8.4.2 "Other RPO's visibility projections" has been added to the proposed plan that was presented at public hearing. The section compares the visibility projections from CENRAP, Visibility Improvement State and Tribal Association of the Southeast (VISTAS), and Midwest Regional Planning Organization (MRPO) for Mingo and Hercules Glades Class I areas. Missouri used CENRAP modeling results in developing the RH plan based on a better quality-assured inventory.

COMMENT #31: The FWS commented that section 6.3 of the draft Missouri Regional Haze Plan discusses the ongoing and future monitoring strategy for measuring visibility parameters and progress at the Class I areas within Missouri. Given the uncertain future of any individual monitoring site, the plan should address the representativeness of both primary and alternative data sites, and also provide a more specific plan for ensuring that monitoring is continued if national funding is not available.
RESPONSE AND EXPLANATION OF CHANGE: This comment on the early draft plan resulted in additional language being added to the proposed plan that was presented at public hearing to address future monitoring if national funding is not available.

COMMENT #32: The FWS encourages Missouri to not only consider the need for monitoring data to measure progress, but also how the plan accounts for and reconciles both unexpected and reasonably foreseeable emissions growth, changes to the geographic distribution of emissions and substantive discrepancies that may be found in emission inventories or other technical bases of the plan.
RESPONSE AND EXPLANATION OF CHANGE: As a result of this comment, section 7.3 was added to the plan with language that commits to periodic reviews and updates of base year inventories and future-year emissions projections.

COMMENT #33: The FWS commented that Chapter 13 of the draft Missouri Regional Haze Plan discusses options for action following the five-year review. This discussion should include

the anticipated criteria that will be used to evaluate the progress at the five-year review and to select the course of action that will be taken based upon that review.
RESPONSE AND EXPLANATION OF CHANGE: As a result of this comment, criteria for evaluating the progress of the RPGs at the five-year review has been added to the plan. A process flow chart with the review criteria and course of action has also been added to the plan. If the monitoring and emission data does not support the RPG projections for Missouri Class I areas, a 5-factor analysis will be conducted at the five-year review.

COMMENT #34: The FWS commented that the draft Missouri Regional Haze Plan refers to appendices of the plan for documentation of the consultation process but the plan lacks discussion of Missouri's decisions based upon the results of those meetings.
RESPONSE AND EXPLANATION OF CHANGE: As a result of this comment, section 4.1 of the plan was expanded to include more discussion of the basis for the decisions that resulted from the consultation process.

COMMENT #35: The FWS commented that the draft Missouri Regional Haze Plan should outline how Missouri would accomplish future ongoing consultation activities if the CENRAP organization no longer existed. Also, the future consultation activities mentioned in the plan should consistently mention the Federal Land Manager agencies as a partner in that consultation.
RESPONSE AND EXPLANATION OF CHANGE: This comment on the early draft plan resulted in additional language being added to the proposed plan that was presented at public hearing stating that ongoing consultation activities would be led by Missouri if the CENRAP organization no longer existed. In addition, language has been added to sections 2.6 and 10.3 of the plan to clarify that federal land managers are included in the consultation process.

COMMENT #36: The FS commented that Chapters 1 and 4 of the Missouri Regional Haze Plan should include the Boundary Waters Canoe Class I area in Minnesota since earlier RPO discussions identified Missouri as effecting visibility in that area. Also, the discussion should clarify what states contributed to achieving reasonable progress in Missouri and an evaluation of the additional Missouri controls that was requested by Minnesota.
RESPONSE AND EXPLANATION OF CHANGE: As a result of this comment on the early draft plan, additional discussion language regarding Boundary Waters was added to section 4 of the proposed plan that was presented at public hearing to clarify the lack of contribution by Missouri on that Class I Area.

COMMENT #37: The FS commented that Chapter 7 of the Missouri Regional Haze Plan should include a discussion of the Area of Influence for the emissions that cause or contribute to visibility impairment in the affected Class I areas and identify those affected areas. The State is required by 40 CFR 51.308(d)(4)(ii) to state the procedures by which monitoring data and other information are used in determining the contribution of emissions from within the state to regional haze visibility impairment at mandatory federal Class I Areas both within and outside the state. It should also be mentioned in the plan if Missouri intends to update the inventory periodically.
RESPONSE AND EXPLANATION OF CHANGE: As a result of this comment and FWS comments on the early draft plan, discussion language in the proposed plan that was presented at public hearing was expanded to include AOI maps, applicable CENRAP graphics, additional

emissions allocation information and attribution of haze-causing pollution that includes results of consultations with neighboring states. In addition, section 7.3 was added to the plan with language that commits to periodic reviews and updates of base year inventories and future-year emissions projections.

COMMENT #38: The FS commented that Chapter 8 of the Missouri Regional Haze Plan should include a discussion of what differences actually occurred in the various RPO inventories used for visibility projections. Then one could assess which modeling scenario best represents impacts at the affected Class I areas.
RESPONSE AND EXPLANATION OF CHANGE: This comment on the early draft plan resulted in additional language being added to section 8.4.2 of the proposed plan that was presented at public hearing to more completely address the land management agency priorities.

COMMENT #39: The FS commented that Chapter 10 of the Missouri Regional Haze Plan states that the 2018 visibility goals for Mingo and Hercules Glades have been largely achieved through EGU emissions reductions and that the four-factor analyses had been conducted by EPA, CENRAP and other RPOs. Although, background and reference material was prepared by these entities, it is the responsibility of the States to apply the four-factor analysis appropriately. EPA also commented that Missouri must include the required four-factor analysis, the results of the analysis and the effect(s) on visibility improvements at Class I areas in the plan.
RESPONSE: Missouri has included the four-factor analyses from CENRAP, and the effects on visibility improvement at Missouri Class I areas in the plan. Additional CENRAP control sensitivity run controls will be considered if the five-year review does not indicate sufficient progress is being met with the proposed controls. No changes were made to the plan as a result of this comment.

COMMENT #40: The FS requested clarification of the status of the Central Class I area consultation since they thought that the consultation had ended.
RESPONSE: The discussion in section 11.2 is referring to subsequent coordination and consultation that will occur in the development of future progress reports and plan revisions, as well as during the implementation of programs having the potential to contribute to visibility impairment in the mandatory Class I areas. No text changes have been made to the plan as a result of this comment.

COMMENT #41: The FS commented that the draft Missouri Regional Haze Plan listed those Class I areas which Missouri would reasonably be anticipated to impact. Such a list in Chapter 11 of the plan would be useful and they recommend including the appropriate list in the plan.
RESPONSE AND EXPLANATION OF CHANGE: As a result of this comment on the early draft plan, discussion language in section 4.1 of the proposed plan that was presented at public hearing was expanded to include a list of impacted Class I Areas.

COMMENT #42: The FS commented that Chapter 11 of the Missouri Regional Haze Plan states that Missouri will include BART controls proposed by the other impacting states in its long term strategy. Since not all of these BART determinations are completed, they want to know what mechanism will be used to adjust the Reasonable Progress Goal based on the other states' final BART determinations.

RESPONSE AND EXPLANATION OF CHANGE: As a result of this comment, section 11.4.1.2 has been revised to reflect that the five-year review will be the mechanism used to adjust the Reasonable Progress Goal based on the other states' final BART determinations.

COMMENT #43: The FS commented that section 11.4.2 of the Missouri Regional Haze Plan refers to the 2018 Reasonable Progress Goals for Mingo and Hercules Glades Class I areas but should refer to the Uniform Rate of Progress goal for 2018. While the CAIR controls are very cost effective, Missouri has made no showing that additional cost effective controls are not available. If Missouri chooses not to consider the CENRAP developed "C1" control strategy, then Missouri should explain its rationale for not selecting a strategy which would achieve greater reductions than its present strategy.
RESPONSE AND EXPLANATION OF CHANGE: As a result of this comment, the language in section 11.4.2 of the plan has been revised to reflect the Uniform Rate of Progress (URP) goal for 2018. Visibility projections based on CENRAP modeling indicate that Missouri will be able to meet the Uniform Rate of Progress goals for both Mingo and Hercules Glades Class I areas during the first planning period ending in 2018. All applicable measures reflected in the modeling and weight of evidence analysis have been incorporated in the state's long-term strategy. Missouri has not selected a strategy to achieve greater reductions than necessary to meet the Uniform Rate of Progress because the state must follow state statute 643.055 that does not allow standards stricter than those required under the provisions of the federal Clean Air Act. Additional cost effective controls including SO_2/NO_X Reasonably Available Control Technology (RACT) in the St Louis $PM_{2.5}$ plan and Illinois Multi-Pollutant Strategy will provide more air quality benefit in visibility improvement. These additional controls were not modeled by CENRAP.

COMMENT #44: The FS commented that section 11.4.5 of the Missouri Regional Haze Plan should include discussion stating that Missouri has not documented smoke contributing significantly to visibility impairment in Class I areas for consistency with the Missouri Smoke Management Plan. Since it appears the current prescribed fire smoke management techniques implemented in Missouri are adequate to protect visibility in the Class I areas and the Missouri Smoke Management Plan should provide additional protection, these points should be noted in the plan discussion.
RESPONSE AND EXPLANATION OF CHANGE: As a result of this comment, additional language was added to section 11.4.5 of the plan stating that Missouri is not aware of any smoke contributing significantly to visibility impairment in Class I areas and that the Missouri Smoke Management Plan should provide additional protection for these areas.

COMMENT #45: The FS suggested that it may be prudent to omit specific elements of the Interim Air Quality Policy from section 11.4.5 of the Missouri Regional Haze Plan to help maintain flexibility for modification since the policy is due to be revised by July 2008.
RESPONSE AND EXPLANATION OF CHANGE: As a result of this comment, the specific elements of the Interim Air Quality Policy has been removed from section 11.4.5 of the plan.

COMMENT #46: The FS commented that Section 13 of the Missouri Regional Haze Plan should contain greater detail relating to judging adequacy of the existing plan. For example, explain how Missouri will determine if the plan is adequate, if the inadequacy is due to

emissions from Missouri or other states/areas and what plan revisions will be made if the inadequacy is due to Missouri sources.
RESPONSE AND EXPLANATION OF CHANGE: Section 13 of the plan already states that the findings of the five-year progress report will determine what plan revisions will be made if it is determined to be inadequate due to Missouri sources. Any resulting plan revisions could include a revision to goals, contingency measures, the monitoring strategy, and any other parts of the plan as deemed necessary. In response to COMMENT #50, criteria has been added to the plan for evaluating the progress to meet the Reasonable Progress Goals in Missouri Class I areas.

COMMENT #47: The FS requested that Missouri consider how the Missouri Regional Haze Plan accounts for and reconciles both unexpected and reasonably foreseeable emissions growth, changes to the geographic distribution of emissions, and substantive discrepancies that may be found in emissions inventories or other technical bases of the state implementation plan. As an example, the predictions of the "IPM" model and the assumptions for CAIR implementation that were used to project the future 2018 electric utility generation industry sources and emissions may be greatly different from the outcomes that are actually realized in that future year. Such factors, as well as other unanticipated circumstances, may adversely affect Missouri's ability to achieve the emissions reductions projected by the plan.
RESPONSE AND EXPLANATION OF CHANGE: As a result of this comment, section 7.3 was added to the plan with language that commits to periodic reviews and updates of base year inventories and future-year emissions projections.

COMMENT #48: The EPA provided a statement at public hearing supporting Missouri's efforts in developing the Missouri Regional Haze Plan. Appreciation was expressed for the opportunity to provide early comment on the draft regional haze plan. They believe that this cooperation resulted in a more efficient and effective plan review process for both the department and the EPA.
RESPONSE: EPA's support for these efforts is appreciated.

COMMENT #49: The EPA commented that the Missouri Regional Haze Plan must include a discussion of what action was taken or not taken in adddressing each Federal Land Manager comment including the rationale for the decisions. The FWS and the FS also anticipate these responses to their questions in accordance with the 40 CFR 51.308(i)(3) requirement.
RESPONSE AND EXPLANATION OF CHANGE: A copy of the comments, along with responses to those comments, have been included in Appendix C of the Missouri Regional Haze Plan.

COMMENT #50: The EPA commented that Section 13 of the Missouri Regional Haze Plan must include a definitive statement that the modeling and monitoring information will be used and the consultation process described in the plan will be followed in carrying out the scheduled incremental administrative and technical actions required in the plan.
RESPONSE AND EXPLANATION OF CHANGE: As a result of this comment, a more definitive statement has been added to Section 13 of the plan.

COMMENT #51: The EPA commented that the Missouri Regional Haze Plan does not contain any information concerning how the plan will be managed throughout its administrative and/or

regulatory life. The plan should identify what Missouri agency and/or official will be responsible for conducting the numerous time critical actions required. The plan should also identify the form(s) or format(s) in which the plan will be maintained. A digital (i.e. computer) format with specific intervals to revisit the format for periodic technology updates is suggested for the long-term plan retention and accessibility. It is also suggested that one or more paper copies of the plan be retained by the State for easy retrieval by the public and others.
RESPONSE AND EXPLANATION OF CHANGE: As a result of this comment, sections 12.0 and 13.0 have been revised to include the suggested information pertaining to plan management. Criteria has also been developed for evaluating the progress to meet the Reasonable Progress Goals in Missouri Class I areas.

COMMENT #52: The EPA commented that Chapter 12 of the Missouri Regional Haze Plan provides no specific information as to actions that will be taken by the State during the important first five-year Reasonable Progress reporting period. The plan should include a discussion of the planned activities during this period.
RESPONSE AND EXPLANATION OF CHANGE: As a result of this comment, sections 12.0 and 13.0 have been revised to include specific information regarding planned activities during the five-year reasonable progress reporting period. Criteria has also been developed for evaluating the progress to meet the Reasonable Progress Goals in Missouri Class I areas.

COMMENT #53: The EPA commented that interstate regional haze consultation discussion in the Missouri Regional Haze Plan is unclear on whether or not there is an agreement between Missouri and the states of Minnesota and Okalahoma over the significance of Missouri's emissions at Class I areas in those states. The status of the consultations between the states, including a discussion of resolved issues, should be provided in the plan.
RESPONSE AND EXPLANATION OF CHANGE: As a result of this comment on the early draft plan, discussion language in section 4.2 of the proposed plan that was presented at public hearing was revised to expand discussion on the disagreement between Minnesota, Oklahoma and Missouri regarding Missouri source influences on the Minnesota and Oklahoma Class I Areas.

COMMENT #54: The EPA commented that the discussion in section 11.4 of the Missouri Regional Haze Plan needs to be clarified as to which programs listed are relied upon to demonstrate that the plan will meet its Reasonable Progress Goal.
RESPONSE AND EXPLANATION OF CHANGE: As a result of this comment, the plan has been revised to specify that "on the book controls" under section 11.4.1. are the only programs used in modeling demonstration in meeting the RPG requirements.

COMMENT #55: The EPA commented that the inventory development discussion in the Missouri Regional Haze Plan should clarify that the department's Air Pollution Control Program and CENRAP, with contractor support, prepared the onroad inventory. Also, Missouri should indicate what entity processed the data used in developing the final onroad inventory. Finally, the inventory development discussion should state whether the 2018 emissions inventory was based on 12 months of data inputs or a different time frame.

RESPONSE AND EXPLANATION OF CHANGE: As a result of this comment, language was added clarifying which entity prepared the onroad mobile emissions inventory and stating that the 2018 emissions inventory was based on 12 months of data inputs.

COMMENT #56: The EPA commented that Table 9.1 in Chapter 9 of the Missouri Regional Haze Plan should be revised to include the dates for facilities, the emissions that make the sources BART-eligible and an evaluation of emission type and amount. These dates should be included since BART-eligible determinations involve consideration of both the "start-up" and "in operation" dates. Missouri should clarify how it determined which sources should undergo further BART modeling analysis. For example, the State should state whether it used the Q/d (emissions divided by distance) approach in deterimining which sources needed to be modeled further or some other approach. EPA commented that Appendix H of the plan is both difficult to read and to extrapolate emission source information. Therefore, both Table 9.1 and Appendix H should be revised to provide emission information and construction dates rather than the "X" that was inserted in certain tabular fields without an explanation.
RESPONSE AND EXPLANATION OF CHANGE: As a result of this comment, Appendix I (original Appendix H) of the plan has been revised to include an explanation of the finding of BART-eligibility, specifically detailing the elimination methodology including date or size of emission source as the rationale. Upon consideration of this comment, the department discovered eight (8) additional sources that were mis-characterized as having no BART eligible sources. The plan has been revised to include these sources in Table 9.1 and the rationale for inclusion or exclusion is detailed in Appendix I (original Appendix H). In response to the portion of the comment regarding Q/d, the department did not use a Q/d approach for eliminating sources but, instead, performed a screening evaluation of all BART-eligible sources in Missouri. The results of the screening analyses were utilized to determine the need for refined CALPUFF modeling.

COMMENT #57: The EPA commented that the information in Chapter 9 of the Missouri Regional Haze Plan needs to clarify the following issues. The plan is unclear as to the regulatory status of Portland Cement Plants in Missouri. The plan suggests that these plants are subject to seasonal limits under the NOx SIP Call but doesn't address SO_2 throughout the year, NO_x during non-ozone months or the applicability to plants in the western part of the state. Since Portland Cement Plants are not affected by CAIR, it doesn't seem appropriate to use the NO_x SIP Call to permanently exclude Portland Cement Plants from review under BART.
RESPONSE AND EXPLANATION OF CHANGE: It was not suggested that Portland Cement Plants are not eligible for BART review due to inclusion in the NOx SIP Call. Chapter 9 of the draft regional haze plan had only identified River Cement as a BART-eligible source due to its installation and operation date and size. This plant was issued a construction permit for a new kiln to replace the existing kilns at this location. Therefore, since the units do not exist that were BART eligible, then the subsequent review is moot. However, review of the other cement kilns in Missouri found that two others had units that were BART-eligible: Continental Cement in Hannibal and Holcim – Clarksville. Continental Cement has been awarded a construction permit for elimination of the existing kiln and the same logic applies to this plant as was applied to River Cement. The Holcim – Clarksville facility is BART-eligible and has screening and refined impacts over the visibility threshold. Currently, the Holcim facility has been asked to evaluate additional controls for SO_2 and NOx including cost of control. This information will be provided

to the department for a decision regarding potential control of the existing kiln at Holcim. Chapter 9 of the plan has been revised to include this discussion.

COMMENT #58: The EPA commented that the information in Appendix H of the Missouri Regional Haze Plan is either incomplete or inconsistent with the State's finding that the River Cement Plant is exempt from further BART review. The plan needs to be revised to address the data omissions and inconsistencies.
RESPONSE AND EXPLANATION OF CHANGE: As a result of this comment, the plan has been revised to address the BART data omissions and inconsistencies.

COMMENTS AND RESPONSES ON
THE 2009 REVISION TO THE MISSOURI REGIONAL HAZE PLAN

On June 25, 2009, the Missouri Air Conservation Commission held a public hearing concerning the 2009 revision to the Missouri Regional Haze Plan. The following is a summary of comments received and the Missouri Department of Natural Resources' corresponding responses. Any changes to the proposed 2009 revision to the plan are identified in the responses to the comments.

The Missouri Department of Natural Resources' Air Pollution Control Program recommends the commission adopt the plan action as amended. If the commission adopts this plan action, it will be the department's intention to submit this revised plan to the U.S. Environmental Protection Agency for inclusion in the Missouri State Implementation Plan.

SUMMARY OF COMMENTS: The department's Air Pollution Control Program received comments from the U.S. Environmental Protection Agency (EPA). Some comments were general in nature and others were specific to the interstate consultation, reasonable progress goal, long-term strategy, and best achievable retrofit technology (BART) sections. Some comments were also specific to the Holcim Cement-Clarksville BART determination and consent agreement.

COMMENT #1: The EPA recommended that the plan, including appendices, be reviewed to assure that it has up-to-date and correct language. As an example, the original plan was submitted to the EPA in March of 2008 but the plan language refers to it as the February 2008 submittal on plan pages 69, 70 and 71. Another example is repetitively listing the BASF facility twice in one sentence on page 58. In addition, the plan mentions documents as being incorporated into an appendix, but the information is not actually in the named appendix in all cases (e.g. Missouri's letter to Doe Run-Glover regarding operating permits).
RESPONSE AND EXPLANATION OF CHANGE: In response to these comments, the plan has been reviewed and updated to reflect the appropriate information.

COMMENT #2: The EPA requested that the reasonable progress, best available control technology equivalency to BART, potential to emit permit limitation and all Holcim BART consent agreement comments to be considered major issue comments.
RESPONSE AND EXPLANATION OF CHANGE: The plan has been reviewed considering the areas identified as major issues and changes were made when deemed necessary and feasible to address these areas.

COMMENT #3: The EPA noted that, since Missouri's Regional Haze Plan is relying on emission reductions from sources in other states in order to meet the 2018 Uniform Rate of Progress (URP) goal for Missouri's Class I areas, Missouri should clearly communicate this reliance to the other states.
RESPONSE AND EXPLANATION OF CHANGE: As a result of this comment, letters will be sent to the states on which Missouri is relying for emission reductions to meet the URP. The letter will reiterate what was concluded during the consultation conference calls regarding Missouri's reliance on other states' emission reductions to meet the URP goal.

COMMENT #4: The EPA requested additional explanation of how the four statutory factors were considered in arriving at the Reasonable Progress Goal for both Missouri Class I areas.
RESPONSE AND EXPLANATION OF CHANGE: To address this comment, section 10 of the plan was rewritten to provide more explanation of the how Missouri achieved the four factor analysis requirement.

COMMENT #5: The EPA requested that section 11.4 of the long term strategy chapter have a reference added to Table 10.1 in order to link it to the reasonable further progress chapter.
RESPONSE AND EXPLANATION OF CHANGE: As suggested, a reference to Table 10.1 was added to section 11.4.

COMMENT #6: The EPA commented that section 11.4.2 should be revised to only list those programs that Missouri is relying on for long term strategy.
RESPONSE AND EXPLANATION OF CHANGE: Only the programs listed in section 11.4.1. are relied upon for Missouri's long term strategy as stated at the beginning of section 11.4.2. As stated in section 11.4.2, the programs listed in section 11.4.2. are additional control strategies not included in the modeling demonstration that may be considered during the five-year review. These programs are retained in section 11.4.2. for future reference. As a result of this comment, additional explanatory language has been added to section 11.4 for additional clarification.

COMMENT #7: The EPA commented that Appendix I of the plan should be revised to provide consistency in the type of information provided.
RESPONSE AND EXPLANATION OF CHANGE: As a result of this comment, Appendix I has been revised so that information provided is presented in a consistent format.

COMMENT #8: The EPA commented that the potential to emit (PTE) limits referenced in this appendix as reasons for exempting sources from BART should be included in the plan in a permanent and enforceable manner.
RESPONSE AND EXPLANATION OF CHANGE: The limits referenced in this comment were for charcoal kiln facilities that were developed after the kilns were required to comply with 10 CSR 10-6.330, Restriction of Emissions from Batch-Type Charcoal Kilns. This rule limits each kiln control system to emission limits of 1.5 pounds per hour of particulate matter and 0.24 pounds per hour of volatile organic compounds; which translates to less than 10 tons per year for both pollutants. The limits are permanent and enforceable because they are in this rule which is part of the Missouri State Implementation Plan (SIP) and, therefore, federally enforceable. The control systems required by implementation of this rule have resulted in dramatically reduced emissions of all air pollutants from the charcoal kiln industry in Missouri. These reductions have have also resulted in many of the kiln facilities to be classified as Basic operating permit sources instead of Part 70 (major) sources. Including these permits in the SIP will not bring additional enforceability to these facilities due to the ongoing requirements contained in the charcoal kiln rule. Therefore, reference to these permits has been removed from Appendix I.

COMMENT #9: The EPA commented that Appendix J is missing a copy of the Doe Run-Glover facility termination letter that is mentioned in the Appendix C responses to comments.
RESPONSE AND EXPLANATION OF CHANGE: As a result of this comment, a copy of the Doe Run-Glover facility termination letter has been added to Appendix J.

COMMENT #10: The EPA commented that some form of technical detail should be provided regarding the Missouri's determination in Section 9.3 that BACT at Doe Run-Buick is equal to or better than BART. Also, using this determination in the plan requires that the permit must be amended to specify and reference the origin of an authority for the emission unit as cited in 40 CFR 70.6(a)(1)(ii).
RESPONSE AND EXPLANATION OF CHANGE: In response to this comment, Section 9.3 has been revised to address the finding for Doe Run-Buick's BART-eligible unit. Specifically, more documentation was provided to establish the BART finding for this unit.

COMMENT #11: The EPA commented that the explanation of how Missouri performed a more robust screening of sources subject to BART should describe how the screening criteria was applied.
RESPONSE: The approach outlined in the plan does not rely on a particular number of impact days that the State found significant enough to require further analysis at a particular Class I area. The refined screening approach used is consistent with other modeling outcomes that evaluate only a particular set of receptors when these receptors are clearly higher and provide the most conservative outcome for the given emissions set. The methodology utilized to perform the refined screening approach only removed the Hercules, Upper Buffalo, and Mammoth Cave Class I areas from consideration for the Noranda source. This was done because the very nearby Mingo Class I area was obviously impacted the most of any of these areas by the Noranda BART-eligible sources. The remaining sources that underwent refined screening were evaluated for the Mingo, Hercules, and Upper Buffalo Class I areas except the sensitivity analyses conducted for Doe Run Buick at Mingo. This refined screening approach was determined primarily based on distance from the relevant Class I areas to each source. No change was made to the plan as a result of this comment.

COMMENT #12: The EPA commented that additional clarifying documentation should be provided describing how Missouri established both the NOx and SO_2 BART limits for Holcim.
RESPONSE: In the comment, EPA asserts that the NOx control efficiencies used by the department are questionable. The comment does not provide a true and accurate representation of the BART finding for NOx as only mid-kiln firing and selective non-catalytic reduction (SNCR) are mentioned. As discussed in the plan, the department found that mid-kiln firing of tires at a 12 percent total fuel rate along with the existing low-NOx burners and cement kiln dust insufflation represent BART. The department also found that the effective use of SNCR on this long-wet kiln had significant uncertainty. This provided further evidence that established BART as mid-kiln firing of tires with a 20 percent reduction in NOx emissions.

EPA claims that the use of wet lime scrubbing at the facility was cost effective and available for the facility and implies that the department should have selected this control as BART for SO_2. In the plan, the department clearly outlines its basis for the removal of scrubbing technology as BART under Section 9.3.8, "The department found the overall net cost per ton of cement produced (~$15/20) was excessive and would have seriously compromised the Clarksville kiln's ability to compete in the cement production market." On page 39130 of the Final Rule for Regional Haze Regulations and Guidelines for BART Determinations published on July 6, 2005; EPA states, "…we recognize there may be unusual circumstances that justify taking into

consideration the conditions of the plant and the economic effects of requiring the use of a given control technology. These effects would include effects on product prices, the market share, and profitability of the source. We did not intend, for example, that the most stringent control alternative must always be selected in that level would cause a plant to shut down…". The statement from the rule characterizes the exact approach used by the department in this instance. Further, the current operational shutdown at the facility supports the use of fuel switching as SO_2 BART (27 percent reduction) at $3/ton cement produced instead of wet scrubbing at nearly $20/ton cement produced. No changes were made to the plan as a result of this comment.

COMMENT #13: The EPA noted that the 30-day rolling average language in the Holcim Cement-Clarksville consent agreement and the plan language are not consistent.
RESPONSE: The plan states that the calculation of these averages will include all hours when the kiln is not operating and those emissions for both pollutants will be entered as zero pounds. The agreement specifies conditions where the kiln is not operating and continuous emission monitoring data is not required to be collected (paragraph 20 of the agreement). This condition was implemented to allow shutdown of the monitoring equipment when the kiln is not operating for an extended period of time. It follows logically that if the kiln is not operating and is sufficiently cooled there will be no emissions of NOx or SO_2. In paragraph 22 of the agreement, Holcim is required to, "…record the hourly CEM data or data supporting lack of kiln operation to demonstrate compliance with the [emission] limits…". The intention of this statement is to allow the use of non-operational, zero emission data as part of the 30-day rolling averages for compliance with the SO_2 and NOx BART limits. Therefore, this is consistent with the language in the plan. No change to the plan was made as a result of this comment.

COMMENT #14: The EPA recommends that the agreement stay in place in the event of a shutdown, or, if the shutdown-termination language is retained, they recommend clarifying that a current or subsequent owner or operator may only utilize post-BART control emissions, if any, for the purposes of netting.
RESPONSE: In the event of a shutdown, Holcim or any subsequent owner will be subject to the agreement until a permanent cessation letter is sent to the department and the owner agrees to terminate all operating and construction permits for the site as outlined in Condition 26(G) of the consent agreement. Once these conditions are met, the source does not exist any longer and is permanently shutdown for the purpose of new source review. This would mean that any new kiln or start-up of the existing kiln would be required to undergo a major source permitting analysis due to the modification requirement of the construction permit regulation. Therefore, the new source would not be allowed to net out of a major review and would be subject to the requirements of best available control technology and visibility impairment analysis under the permitting regulations. The department would only allow post-BART control emissions for any netting of a new source at this site. No change was made to the plan as a result of this comment.

Appendix D

MACC Adoption Certification

Pursuant to 643.055 RSMo, the Missouri Air Conservation Commission has determined that this action is needed to have a U.S. Environmental Protection Agency approved State Implementation Plan.

The Missouri Regional Haze Plan is hereby adopted by the Missouri Air Conservation Commission this 7th day of February, 2008.

Appendix E

Central Class I Areas Consultation Plan

UNITED STATES
Central Class I Areas Consultation Plan

Scope

This consultation plan establishes the objectives, activities, and timelines to facilitate stakeholder input for meeting visibility requirements in the federal Regional Haze Rule for the following federal Class I areas:

- Hercules Glades Wilderness Area (Missouri)
- Mingo Wilderness Area (Missouri)
- Caney Creek Wilderness Area (Arkansas)
- Upper Buffalo Wilderness Area (Arkansas)

Background

The U.S. Environmental Protection Agency (EPA) promulgated the federal Regional Haze Rule on July 1, 1999. The federal Regional Haze Rule and the Clean Air Act require consultation between the states, tribes, and the Federal Land Managers (FLM) for managing Class I areas. Since regional haze often results from pollution emitted across broad regions, this multi-state planning effort will help in developing the most cost-effective controls for regional haze. This consultation process will provide a coordinated effort to achieve the federal visibility requirements and aid in developing regional strategies for meeting progress goals.

Plan Objectives

This consultation plan provides state air quality agencies with technical information including emission sources, modeling analysis, and source apportionment for Missouri and Arkansas' Class I areas. These state agencies are being given the opportunity to review this analysis and to participate in consultation to develop plans for meeting regional haze reduction requirements for these Class I areas. Regional Planning Organizations (RPOs), FLMs, and the EPA will also be contacted with the opportunity to participate in the development of actions and control strategies for meeting the federal Regional Haze Rule requirements. This plan includes:

1. Consultation Process
2. Technical Analyses
3. Agency Roles/Responsibilities

1. Consultation Process

Consultation discussion will focus on the primary reasonable progress issues including:

- Source area identifications
- State contribution apportionment
- Emission management strategies

The consultation process will be initiated in early 2007. Draft and final documents will be circulated via email to participating consulting agencies. After the initial kick-off, most consultation discussions will occur through conference calls. However, there will be some instances where a meeting may be desirable (e.g. unresolved issues, complex technical discussions, etc.).

The Missouri Department of Natural Resources' Air Pollution Control Program will work with the Arkansas Department of Environmental Quality and the Central States Regional Air Partnership (CENRAP) to set up conference calls/meetings for the consultation process. Technical documents will be provided for discussion before conference calls or meetings.

Draft and final documents will include supporting materials that describe analytical methods, assumptions, and conclusions that were relied upon in developing the documents. Comments on any draft documents will be requested from the consultation group members.

All consultation activities will be documented, including who participated in consultation discussions and on what dates, outcomes of consultation discussions (issues agreed, disagreed, resolutions) and justification for long term strategy. Each contributing state will be requested to share documentation confirming implementation of emission controls being relied on to meet regional haze Uniform Reasonable Progress (URP) goals.

Documents and consultation logs will be posted on the Missouri Department of Natural Resources' Air Pollution Control Program website for public viewing. All conference call/meeting minutes will also be posted on the agency website. When new documents are posted on the website, the Missouri Department of Natural Resources' Air Pollution Control Program will email all consultation participants to inform them that new information has been posted.

MDNR/ADEQ will work with the FLMs and EPA for consultation through conference calls/meeting. This will include an opportunity for consultation with FLMs in person and at least 60 days prior to holding any public hearing on a state implementation plan as required by federal rule.

Action Items

Participate in kick-off
Comment on the draft consultation plan

Confirm emissions inventory and planned control activities
Develop/share individual state timelines for control implementation
Develop/share control progress
Other actions as needed

Reconciliation of Unresolved Issues

If a contributing state/tribe cannot agree with the lead agency establishing the reasonable progress goal, then certain actions will be taken to resolve the disagreement. These actions are as follows:

- Discuss position and supporting documentation
- If still unresolved, elevate to necessary decision makers
- If still unresolved, document disagreement by describing issue(s) in a letter to the EPA, including regional offices and the Office of Air Quality Planning and Standards

All issues must be addressed and incorporated into the long-term strategy. These outreach efforts will also be documented in the state implementation plan.

Contact Information

Contact information is provided in Attachment A.

Continued Consultation

Consultation between the States and the FLMs will continue as the federal Regional Haze program progresses. The consultation will continue in a similar manner via participation in an RPO. This effort will include development and review of SIP revisions and 5-year progress reports. It will also provide for consideration of any other programs that are implemented and have the potential to contribute to impairment of visibility in Class I areas.

Consultation Timeline

Below, in Table 1, is the consultation process timeline that will be used to achieve milestones for consultation on the federal Regional Haze program.

2. Technical Analyses

In assisting the states/tribes in developing regional haze control strategies for Class I areas within CENRAP states and tribes, CENRAP has contracted Environ/Alpine to conduct the modeling and other technical analyses. Alpine assembled available information that was useful in quantifying the reduction in individual fine particulate aerosol species concentrations needed to

satisfy the URP goals. Pertinent “attribution of haze” documents were evaluated. These documents include CENRAP Comprehensive Air Quality Model with extensions (CAMx)/Community Multiscale Air Quality (CMAQ) modeling system visibility modeling results, fine particulate modeling results for the central US, and other technical reports, papers, and analyses bearing directly on the quantification of emissions-source/visibility-receptor impacts at the ten CENRAP Class I and twelve adjoining areas.

Current Regional Haze modeling continues to indicate visibility shortfalls to reaching the necessary URP goals for deciview increments for some of the Central Class I areas in CENRAP. A deciview is a haze index used to quantify incremental changes in visibility perception, where higher deciview values indicate greater levels of visibility impairment. In some of the areas,

Table 1: Consultation Process Timeline

2006 Fall	2006 Winter	2007 Early Spring	2007 Spring	2007 Late Spring	2007 Summer
Develop Baseline and URP Goals	Develop a Consultation Plan	Initiate Collaboration with States	Develop Long Term Strategy (LTS)	Negotiate Changes to LTS	Document Consultation
Back trajectory & Factor analysis	Identify issues for discussion	Consultation log	Follow consultation plan	Emission reduction requirements/ strategies	Who met and when (FLM, RPO, EPA) and discussion
Identify probable area of influence	Review baseline, URP goals, and emissions reduction targets	Discuss URP Goals & contributions assessment	Discuss emissions reduction strategies	Emission budget discrepancies	Consultation outcome Issues agreed, disagreed, resolutions
Apportion state contributions	Develop Action items	Follow consultation plan	Consult with FLM & EPA	Tribal Impacts	Justification of LTS
Develop initial emission cuts to meet 2018 URP Goals	Issues for FLM & EPA input	Consult with FLM & EPA (thru RPO?)	Note areas of irreconcilable disagreement	Additional control strategies	
	Timetable for resolution	Evaluate and identify sources upwind (BART, non-BART, CAMR, other)			

URP goals are expected to be met based on modeling results, but consultation may be necessary to ensure that the emission reductions used in the modeling are actually planned to occur.

Individual Class I Area Characteristics

The Central Class I areas each have individual characteristics. Individual examination of each area elicits a greater understanding of how the Regional Haze problem affects each, and what aspects are of greatest significance.

Hercules Glades

Situated in extreme southwest Missouri, Taney County, Hercules Glades is managed by the United States Department of Agriculture (USDA) Forest Service. The area is 12,315 acres and in some of the most rugged hills of the Missouri Ozarks. The closest urban area is the Springfield/Branson metropolitan statistical area, 40 miles to the west/northwest.

Mingo National Wildlife Refuge

The Mingo National Wildlife Refuge is managed by the federal Fish and Wildlife Service. The Refuge is situated in the Mississippi Flyway. Only part of it is a Class I area (7,730 acres). Memphis to the south and St. Louis to the north are some of the largest urban areas nearby, although there are a few smaller population centers mostly to the east. Proximity to sources in the Ohio River Valley is a consideration.

Upper Buffalo National Area

The Upper Buffalo Class I area (2,200 acres) is managed by the National Park Service in conjunction with overseeing the Buffalo National River. This area in north central Arkansas is south of Springfield, Missouri and east of Fayetteville and Fort Smith. It is an area of low mountains and largely forested, with bisecting streams.

Caney Creek Class I Area

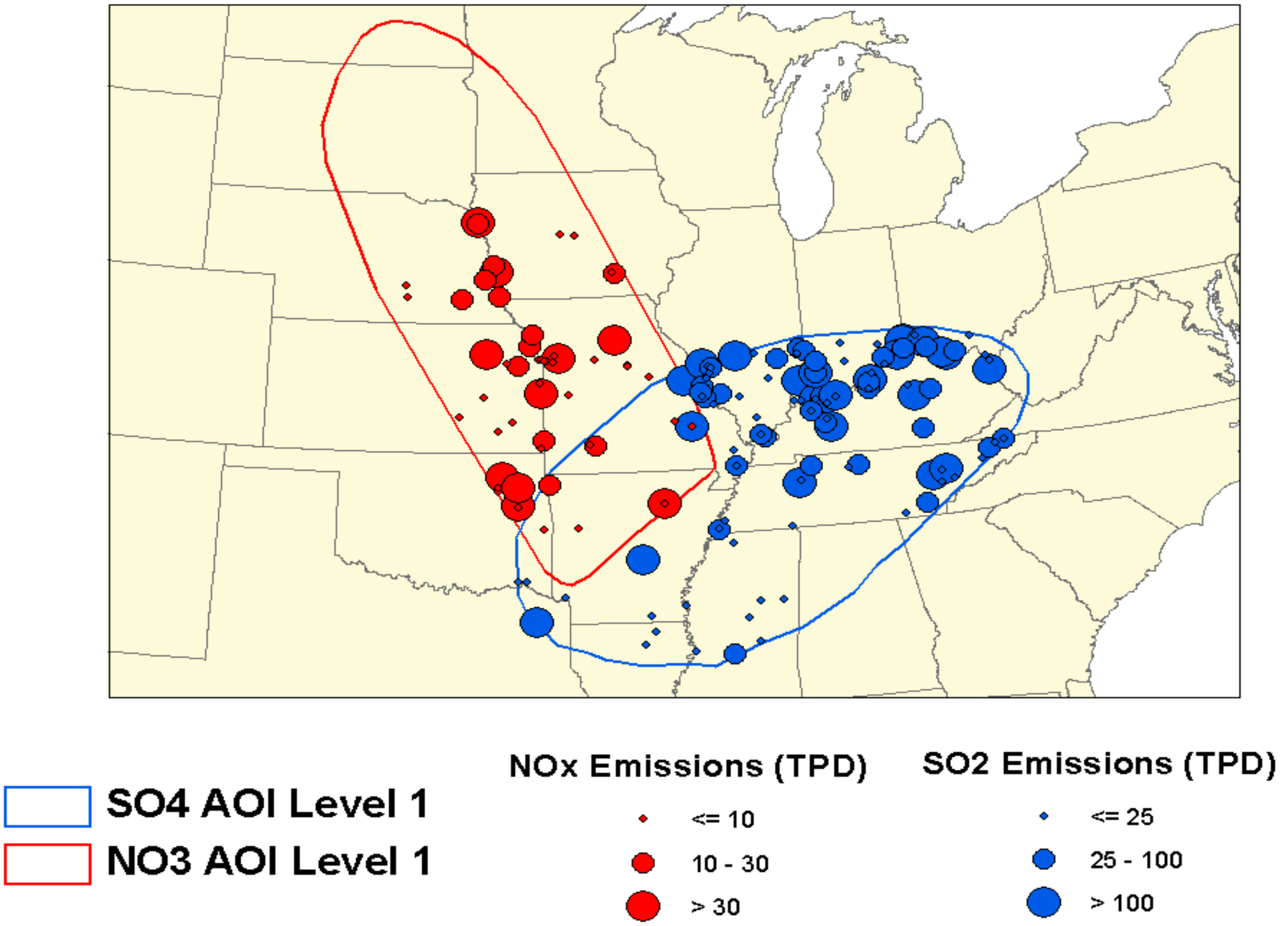
Caney Creek is a 14,460 acre area in the Oachita Mountains of west-southwest Arkansas, the tallest mountain range between the Appalachians and the Rockies. It is south of Fort Smith and west of Little Rock. The area is managed by the USDA Forest Service.

Identification of Source Areas (Areas of Influence)

Source areas must be determined in order to focus the consultation process. That is, locations of significant sources that are likely to affect each Class I area must be identified, and sources within those areas considered for control. Alpine, under its contract to CENRAP, identified Areas of Influence (AOIs), using a variety of data and analyses. In combining the AOI information with emission inventories for the areas, we are able to identify a number of large sources which are of interest.

Figure 1 indicates two Level I AOI's for the Central Class I Areas, one for nitrate (NO_3), and a second grouped collectively for sulfate (SO_4), elemental carbon (EC), organic carbon (OC), coarse mass, and fine soil, along with indicators for sources contained in those areas.

Figure 1 – Alpine AOI's for Central Class I Areas



Attachment B identifies total emissions reductions necessary for level 1 AOI's based on control of sulfate and nitrate species across all four Class I areas. Attachment B also includes inventory tables developed listing possible sources where emissions can be reduced in each state to meet the goals. These emissions provide an overall frame of reference for any reductions in those species.

Contributing States

Source apportionments have recently been conducted on modeling (using Particulate Matter Source Apportionment Technology; PSAT, a source apportionment tool implemented in CAMx) and monitoring data (using positive matrix factorization; PMF/Trajectories) for all four Class I Areas. Attachment C provides both model and monitoring data source apportionment results. Attachment D provides a list of results for Q/D (emissions/distance) used as a third analysis measure. All these, along with Alpine sulfate AOI's described above have been analyzed in tables in attachment E to determine a list of contributing states for each Class I area.

Methodology

Table 2 and 3 (for illustration) below indicate the overall (average) significant contributing states to decreased visibility due to sulfate and nitrate precursor emissions at the Mingo Site. A decision on whether a given state was a contributor was based on the combined analysis results of the four approaches, i.e., PMF/Trajectories, AOI, PSAT, and Q/D. If a state is found to be a major contributor in at least 3 of the 4 approaches, it is believed that inclusion of this state is appropriate. All states in red/bold in the Average row are determined to have sources that are significant contributors to decreased visibility.

Specific to each analysis type, inclusion of a state under the PMF/Trajectories approach depended on the level of probability that an air mass originated from the state during the days of high contribution by sulfate or nitrate sources where the emission impact potential was significant. A state with a high potential of emission impact would be considered a significant contributor.

States were included in the AOI listing if they were part of the level 1 group as determined by Alpine Geophysics. This AOI was based primarily on residence time of air masses, along with evaluation of source emissions of, in this case, nitrate and sulfate.

PSAT analysis was determined based on the 2018 Modeled sulfate and nitrate contribution to average extinction for the 20% worst days. Any state with the contribution of 2.0 deciview or higher was identified as a candidate.

Lastly, Q/D was determined by dividing total SO_2 and NO2 precursor emissions for the state by distance from a state geographic centroid. If totals were less than 200, the state was not indicated as a significant contributor under Q/D.

State in Red/Bold = Major Contributing States

State list

Following are lists of the contributing states for Central Class 1 Areas in Missouri and Arkansas based on the analysis described above;

Hercules Glades

Missouri, Illinois, Indiana, Kentucky, Tennessee, Arkansas, and Texas

Mingo National Wildlife Refuge

Missouri, Illinois, Indiana, Ohio, Kentucky, Tennessee, Arkansas, and Texas

Upper Buffalo National Area

Missouri, Illinois, Indiana, Ohio, Kentucky, Tennessee, Arkansas, Oklahoma, and Texas

Caney Creek Class I Area

Missouri, Illinois, Indiana, Kentucky, Tennessee, Arkansas, Oklahoma, and Texas

3. Agency Roles/Responsibilities

The agencies listed in this section are being requested to participate in the consultation process for the federal Regional Haze Rule. Part of this process is the opportunity for States to review the foregoing analysis and the attachments to this plan and provide feedback, and to consider necessary controls available that will assist in meeting the goals prescribed by the regional haze requirements. Federally enforceable measures to control emissions and thereby achieve the URP will be our ultimate measure of success.

Proposed Roles and/or responsibilities are as follows:

- Missouri Department of Natural Resources' Air Pollution Control Program
  - Co-lead consultation effort for Central Class I areas (Missouri and Arkansas) (i.e. schedule conference calls/meetings, etc. and lead discussions)
  - Evaluate regional haze modeling for reasonable progress
  - Evaluate emissions data
  - Identify air pollutants for Missouri Class I areas
  - Evaluate back trajectory analysis
  - Evaluate probable source area identifications
  - Evaluate state contribution apportionment
  - Share upwind source information (including Best Achievable Retrofit Technology (BART), non-BART, Clean Air Mercury Rule (CAMR), etc.)

- Determine emission management strategies necessary to meet federal Regional Haze Rule requirements
- Provide detailed description of methods used in the SIP to calculate baseline, natural condition, and uniform rate (including supporting documentation for any methods that are not previously established, documented, or supported)
- Document consultation process

- Arkansas Department of Environmental Quality
  - Co-lead consultation effort for Central Class I areas (Missouri and Arkansas) (i.e. schedule conference calls/meetings, etc. and lead discussions)
  - Evaluate regional haze modeling for reasonable progress
  - Evaluate emissions data
  - Identify air pollutants for Arkansas Class I areas
  - Evaluate back trajectory analysis
  - Evaluate probable source area identifications
  - Evaluate state contribution apportionment
  - Share upwind source information (including BART, non-BART, CAMR, etc.)
  - Determine emission management strategies necessary to meet federal Regional Haze Rule requirements
  - Document consultation process
- Illinois Environmental Protection Agency, Ohio Environmental Protection Agency, Indiana Department of Environmental Management, Kentucky Department of Environmental Protection, Tennessee Department of Environment and Conservation, Oklahoma Division of Environmental Quality, Iowa Department of Natural Resources, Kansas Department of Health and Environment, Texas Commission on Environmental Quality, and Louisiana Department of Environmental Quality
- United Keetoowah Band of Cherokee Indians in Oklahoma, Eastern Shawnee Tribe of Oklahoma, Alabama Coushatta Tribe of Texas, Sac and Fox Nation of Missouri, Kickapoo Tribe in Kansas, Potawatomi Nation
  - Participate in consultation effort for Central Class I areas (Missouri and Arkansas) (i.e. conference calls/meetings, discussions, etc.)
  - Provide feedback on reasonable progress analysis (modeling, emissions data, back trajectory, source area identifications, state contribution apportionment)
  - Share upwind source information (including BART, non-BART, CAMR, etc.)
  - Determine emission management strategies necessary to meet federal Regional Haze Rule requirements
- EPA
  - Participate in consultation effort for Central Class I areas (Missouri and Arkansas) (i.e. conference calls/meetings, discussions, etc.)
  - Provide comments on approvability of consultation plan
  - Provide reconciliation on unresolved issues

- FLMs (US Fish and Wildlife Service, National Park Service and the US DA Forest Service)
  - Participate in consultation effort for Central Class I areas (Missouri and Arkansas) (i.e. conference calls/meetings, discussions, etc.)
  - Provide feedback on reasonable progress analysis (modeling, emissions data, back trajectory, source area identifications, state contribution apportionment)
  - Provide feedback on controls necessary to meet federal Regional Haze Rule requirements
- Regional Planning Organization
  - Participate in consultation effort for Central Class I areas (Missouri and Arkansas) (i.e. conference calls/meetings, discussions, etc.)
  - Provide updates and summaries of any work in process (e.g. development of baselines and natural conditions, inventories, modeling efforts and contribution assessments)

Attachment A

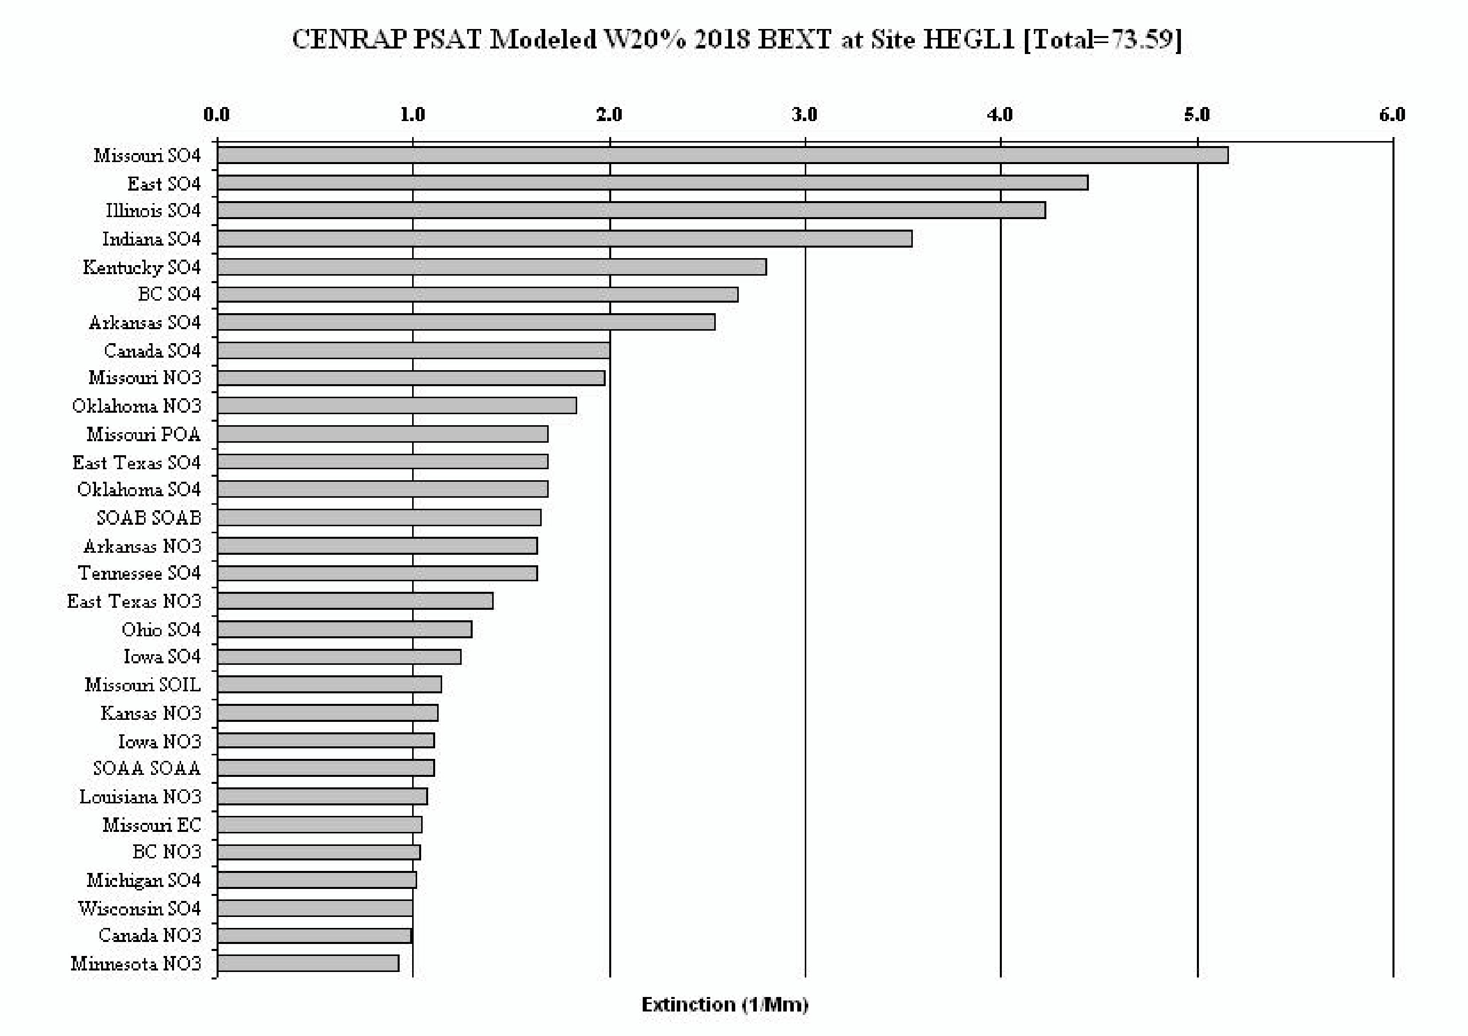
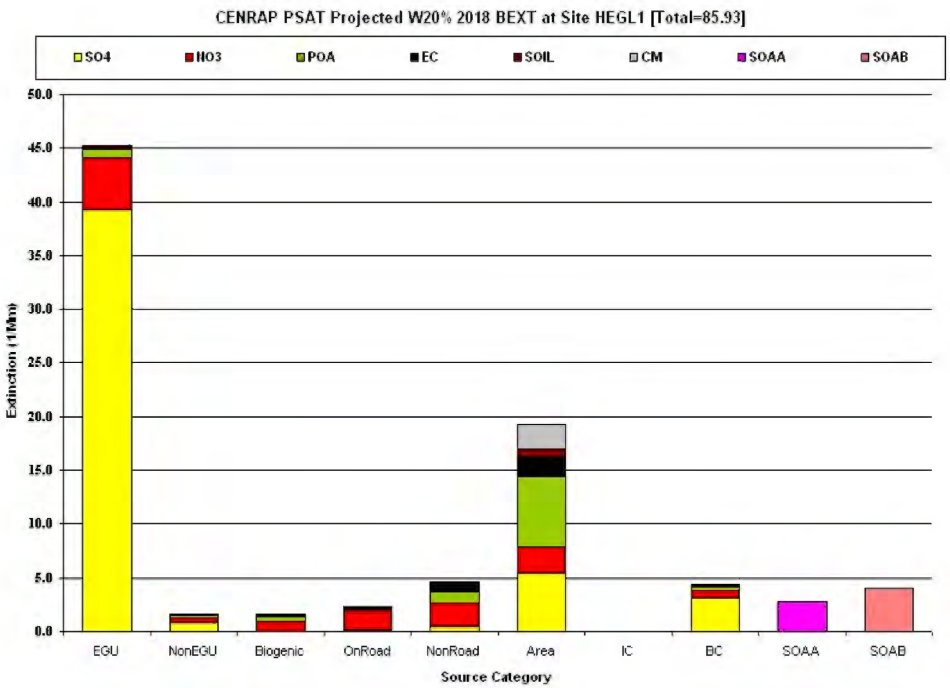
Attachment C – Source Apportionment Analysis

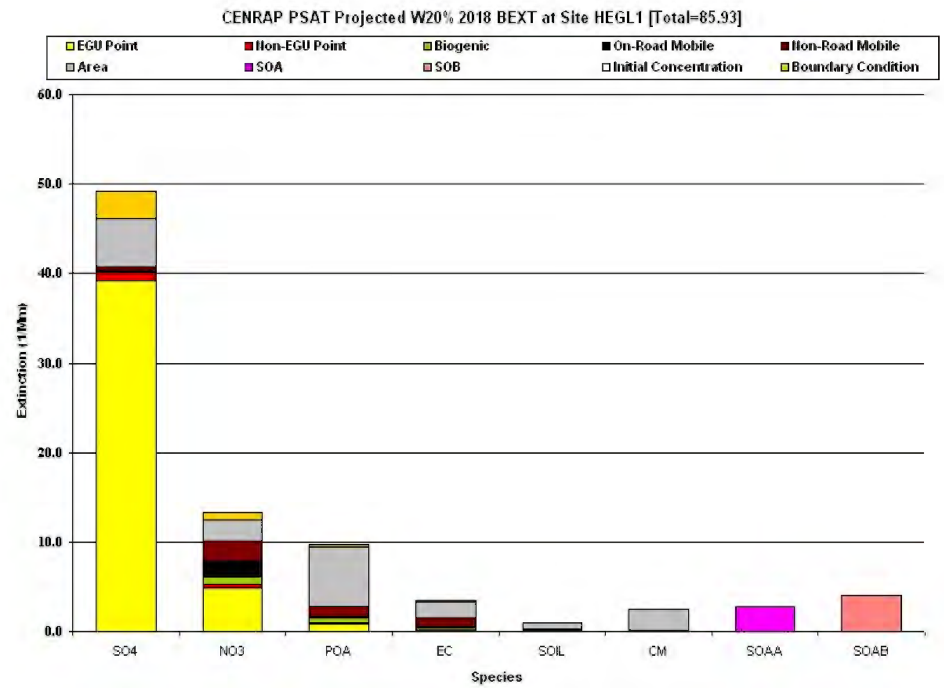
Source Apportionment for the Hercules Glades Class I Area

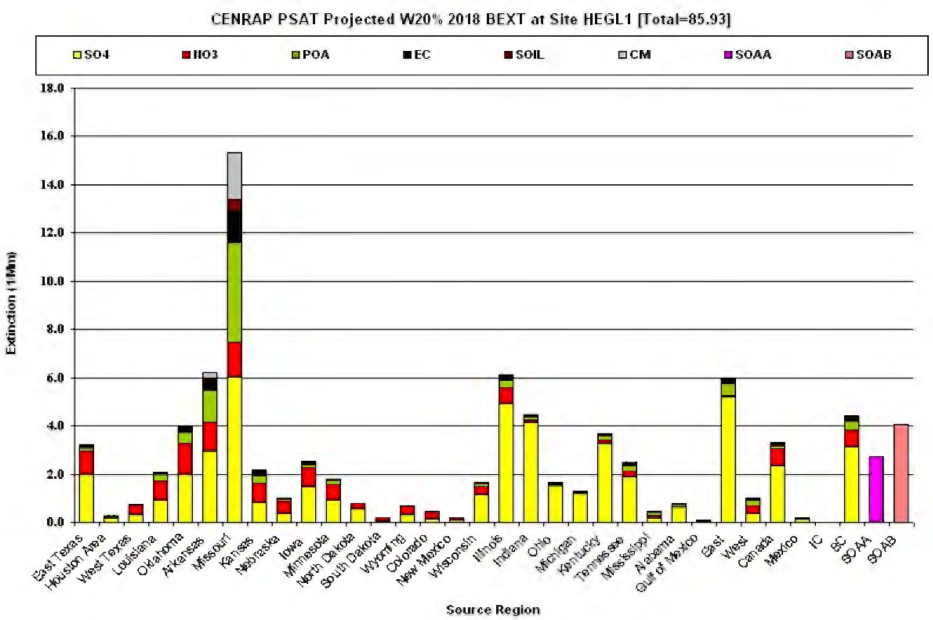
PSAT Model Source Apportionment

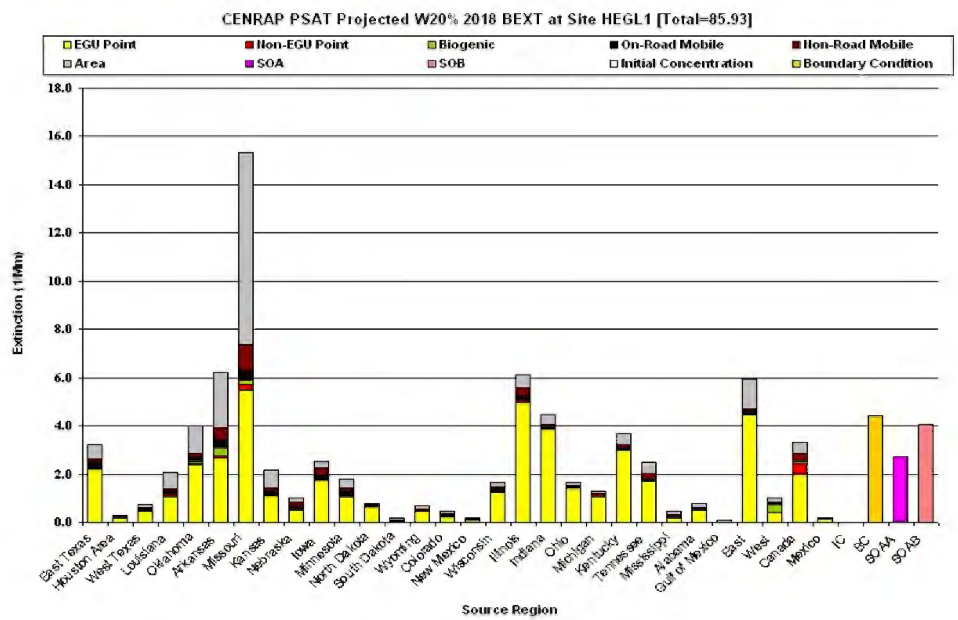


Hercules Glades Projected 2018 – Worst 20%



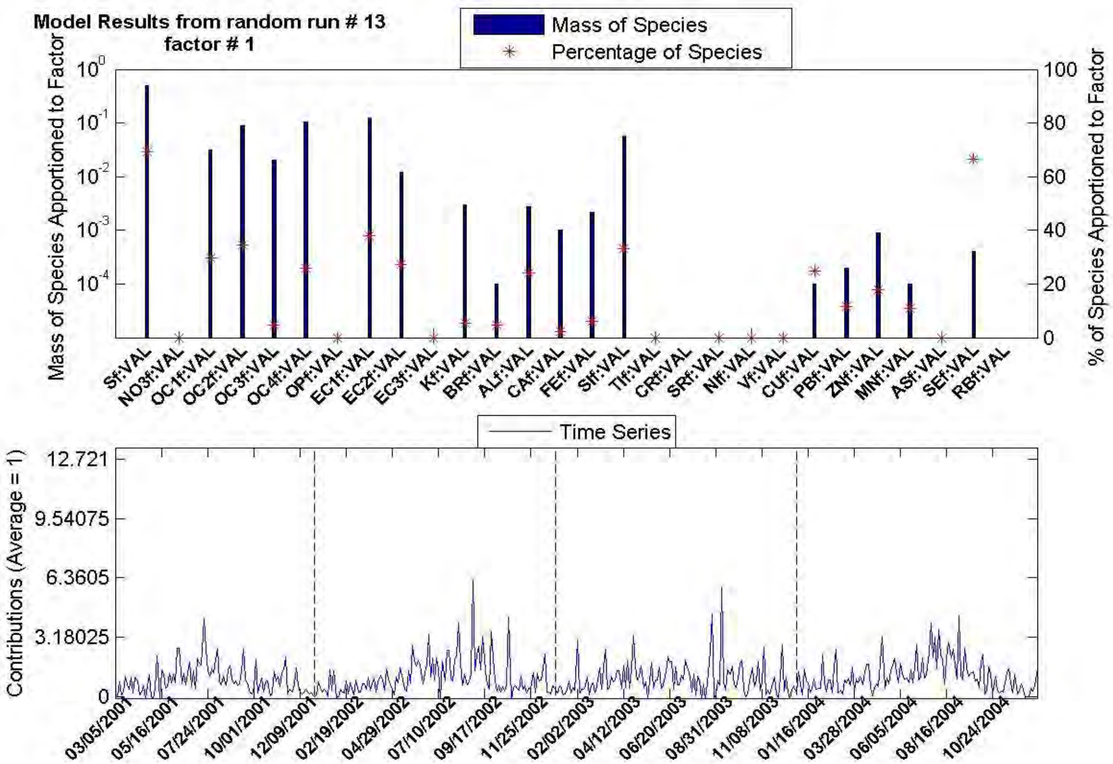




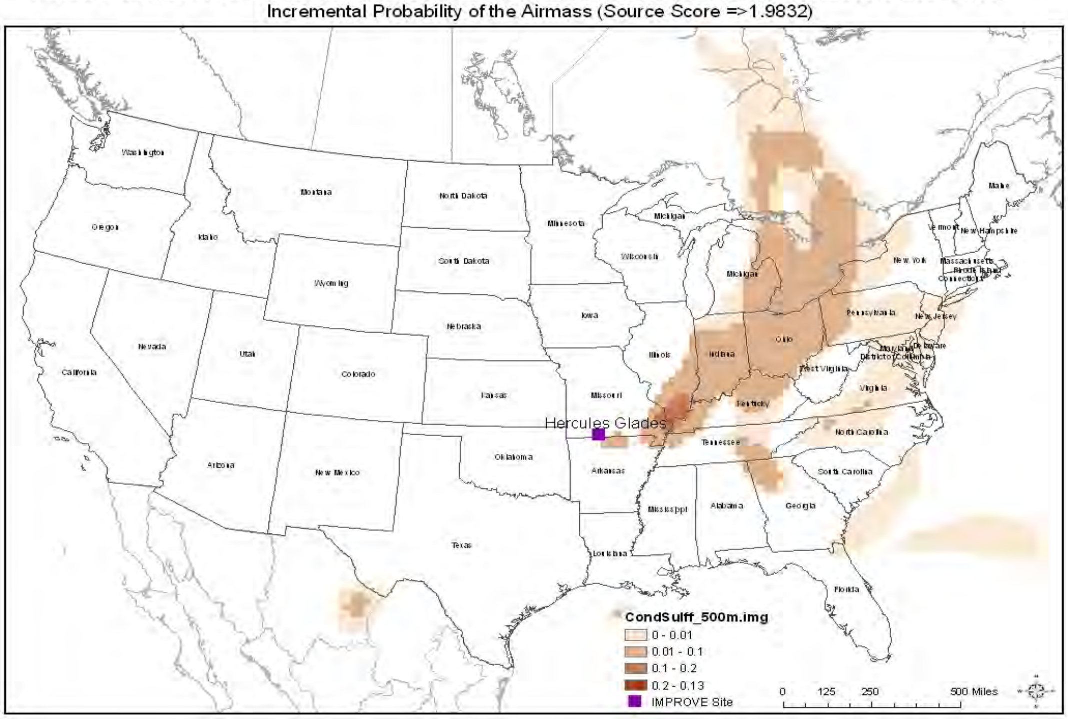


Monitoring Data Source Apportionment

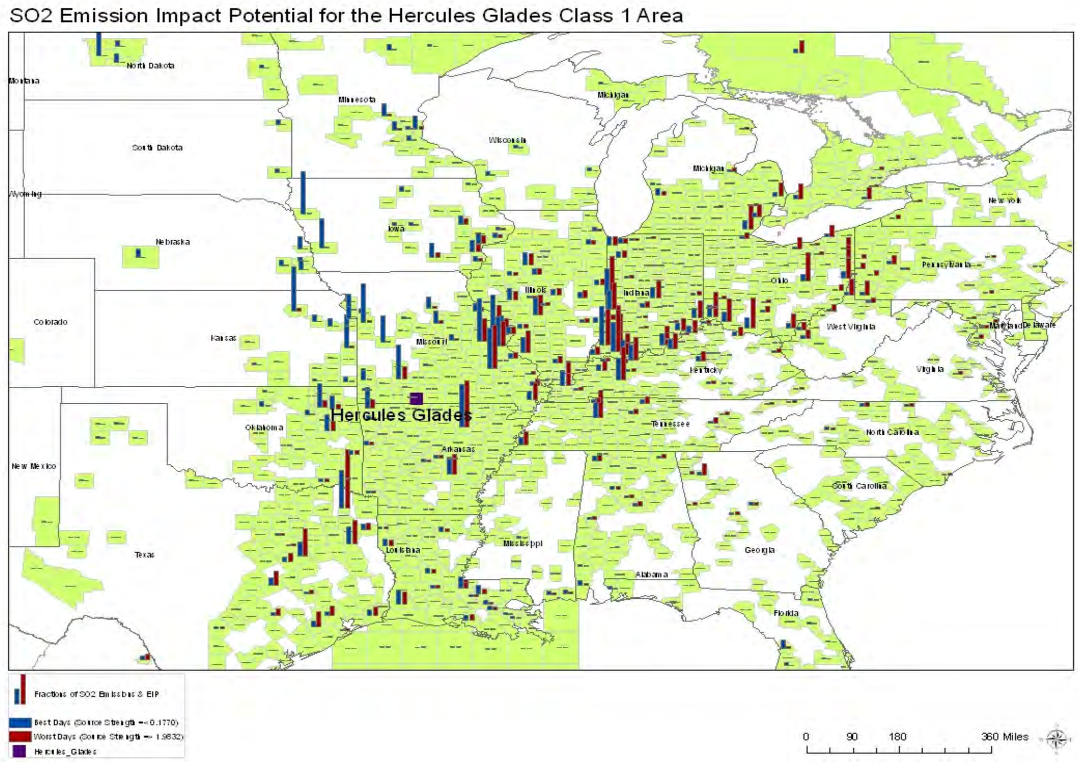
The Coal Combustion Factor at the Hercules Glades Class I Area

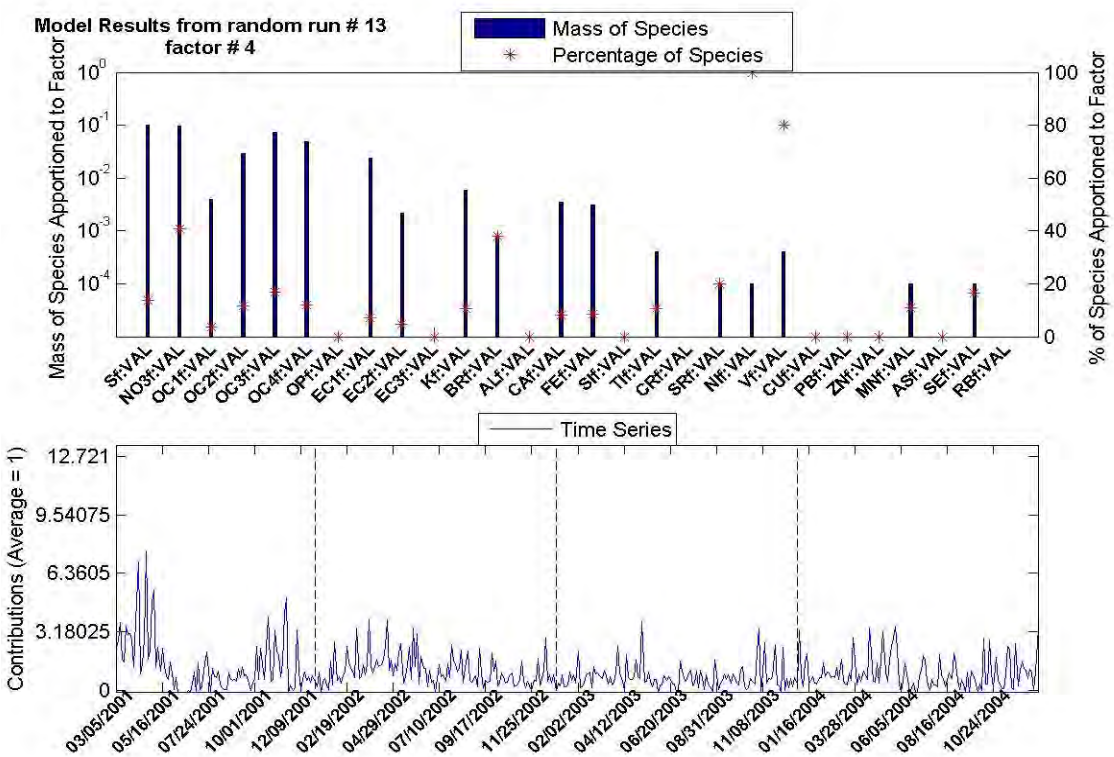


Possible Source Area of the Identified Coal Combustion Factor at the Hercules Glades Class I Area
Incremental Probability of the Airmass (Source Score =>1.9832)

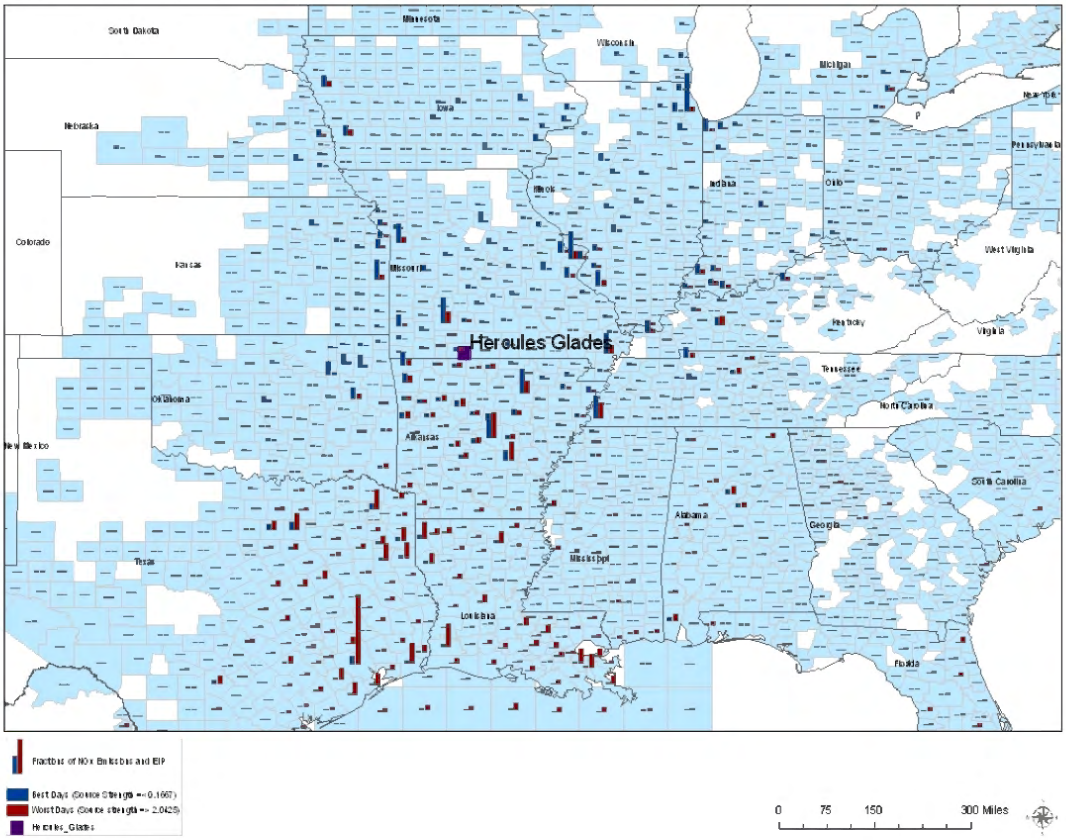


The Secondary Nitrate plus Oil Combustion Factor at the Hercules Glades Class I Area

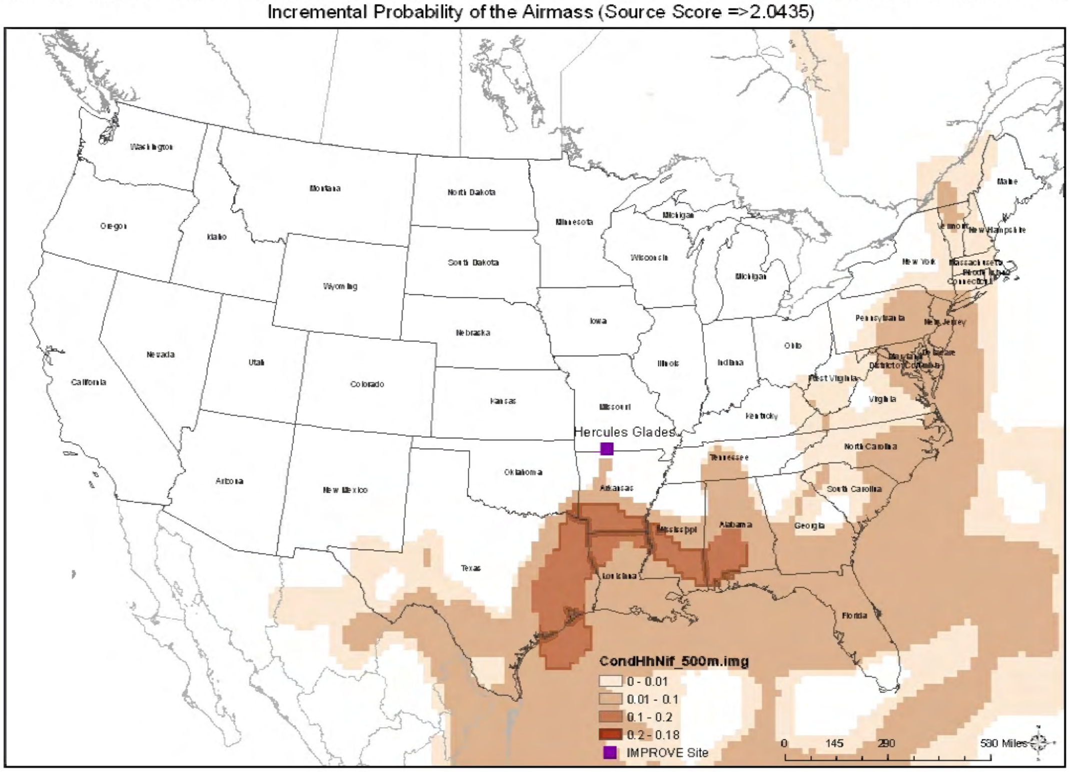




NOx Emission Impact Potential for the Hercules Glades Class I Area

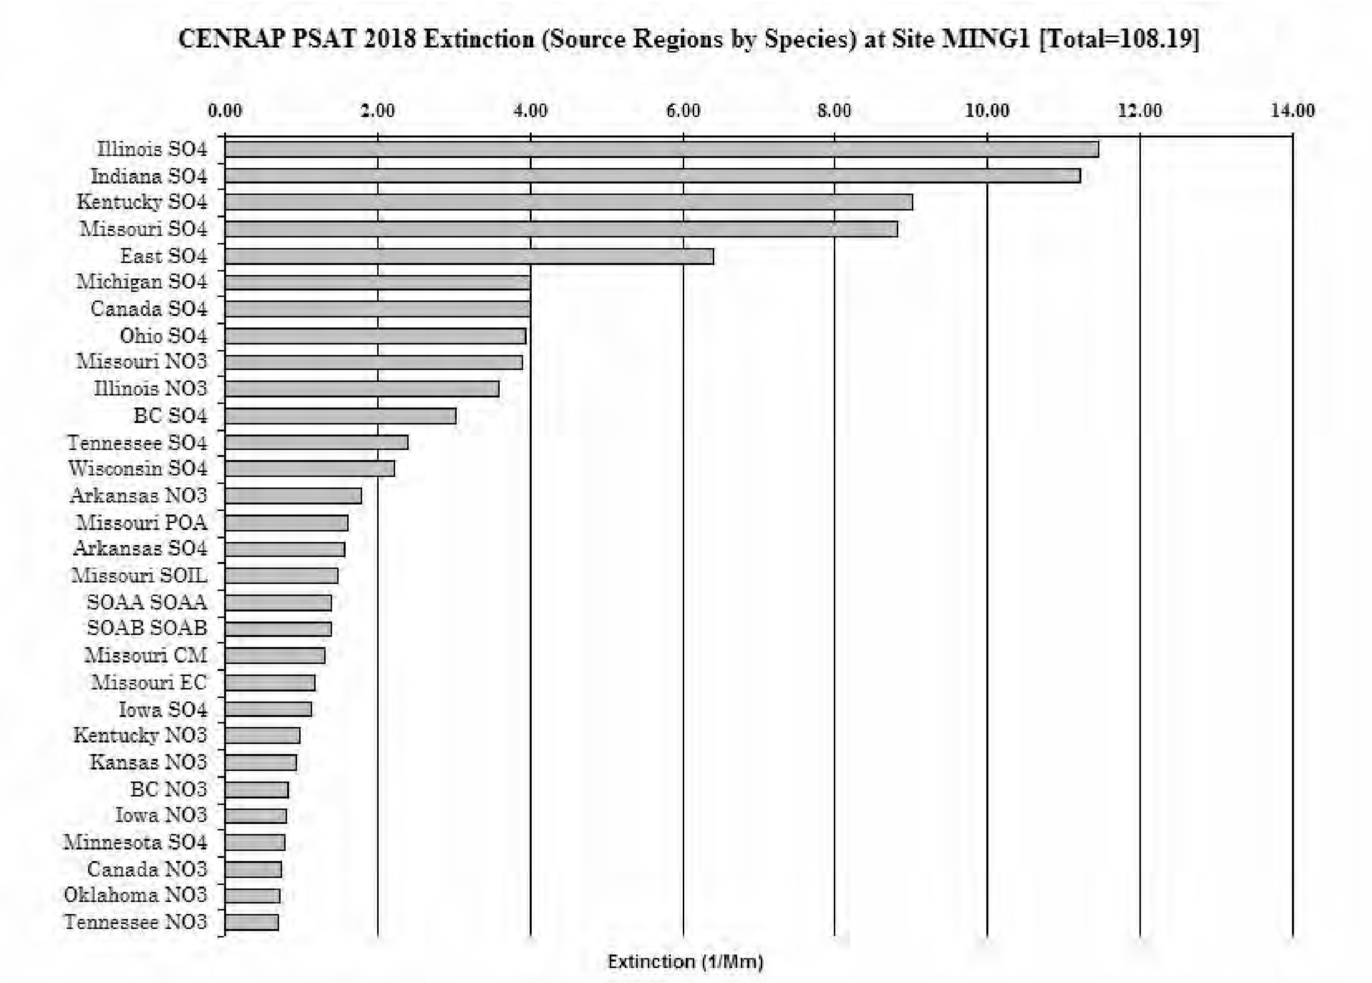


Possible Source Area of the Identified Nitrate Plus Oil Combustion Factor at the Hercules Glades Class I Area
Incremental Probability of the Airmass (Source Score =>2.0435)

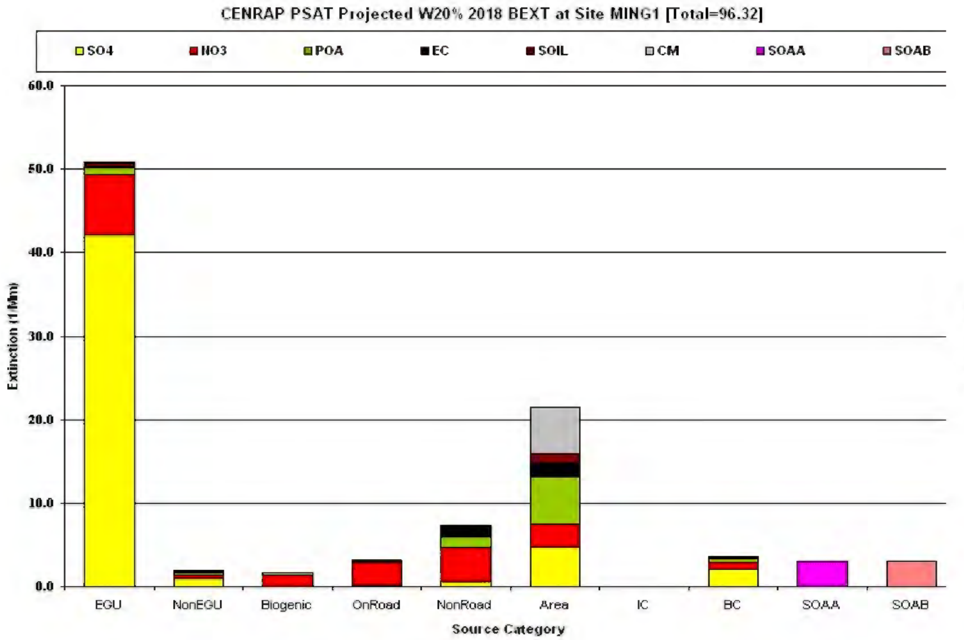


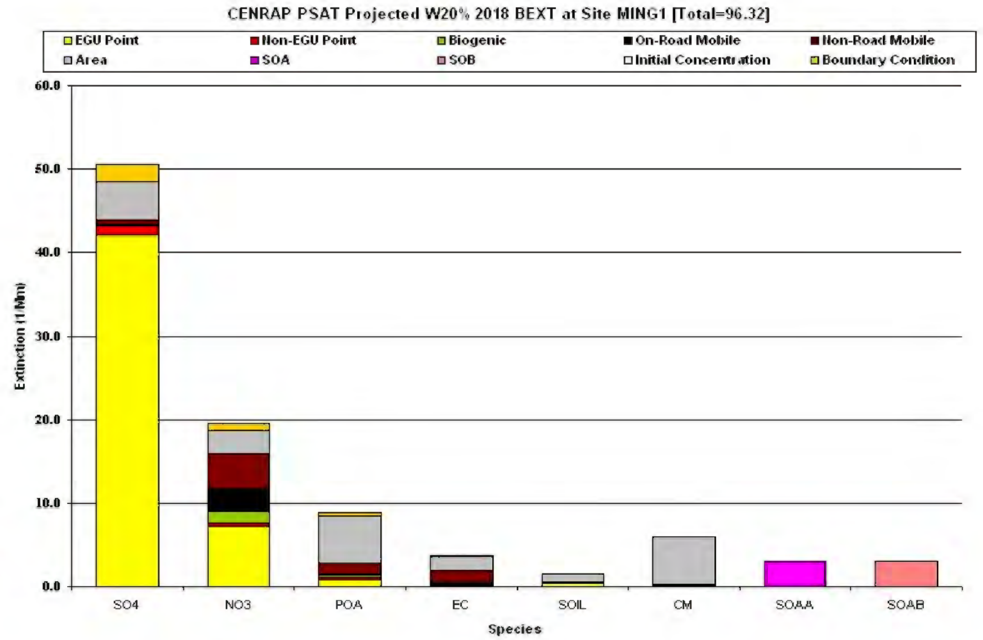
Source Apportionment for the Mingo Class I Area

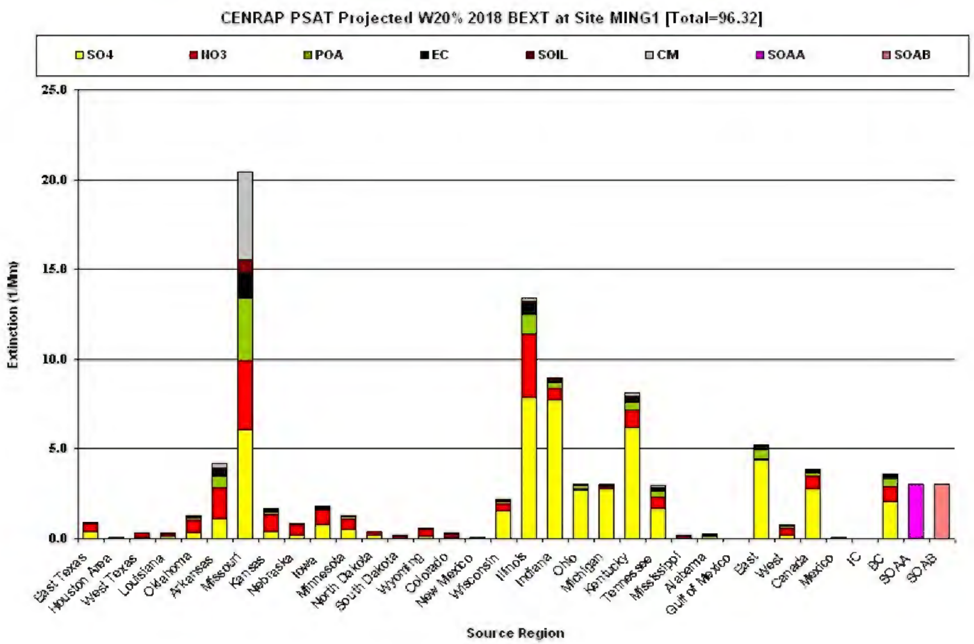
PSAT Model Source Apportionment

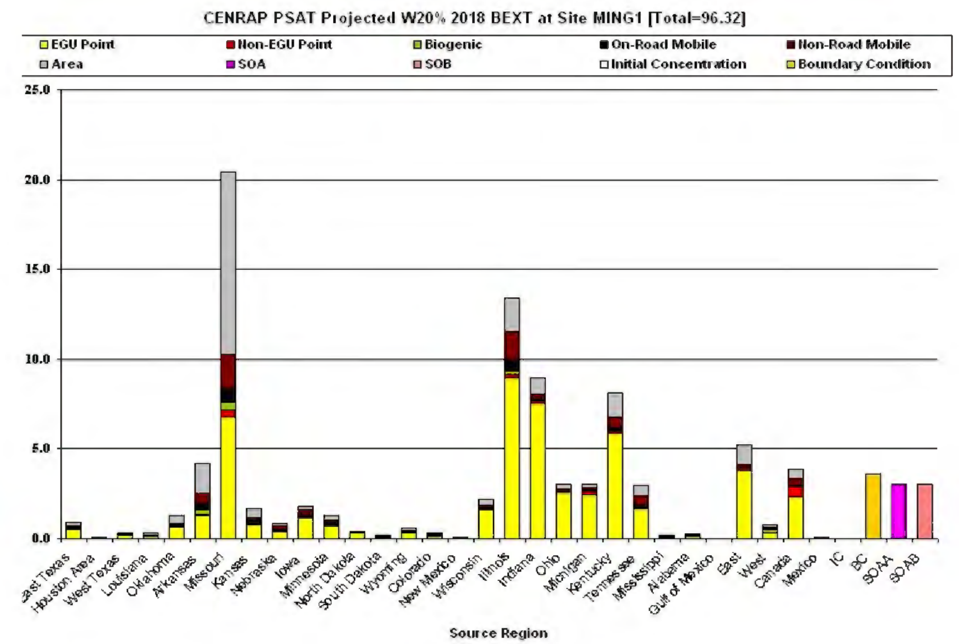


Mingo Projected 2018 – Worst 20%



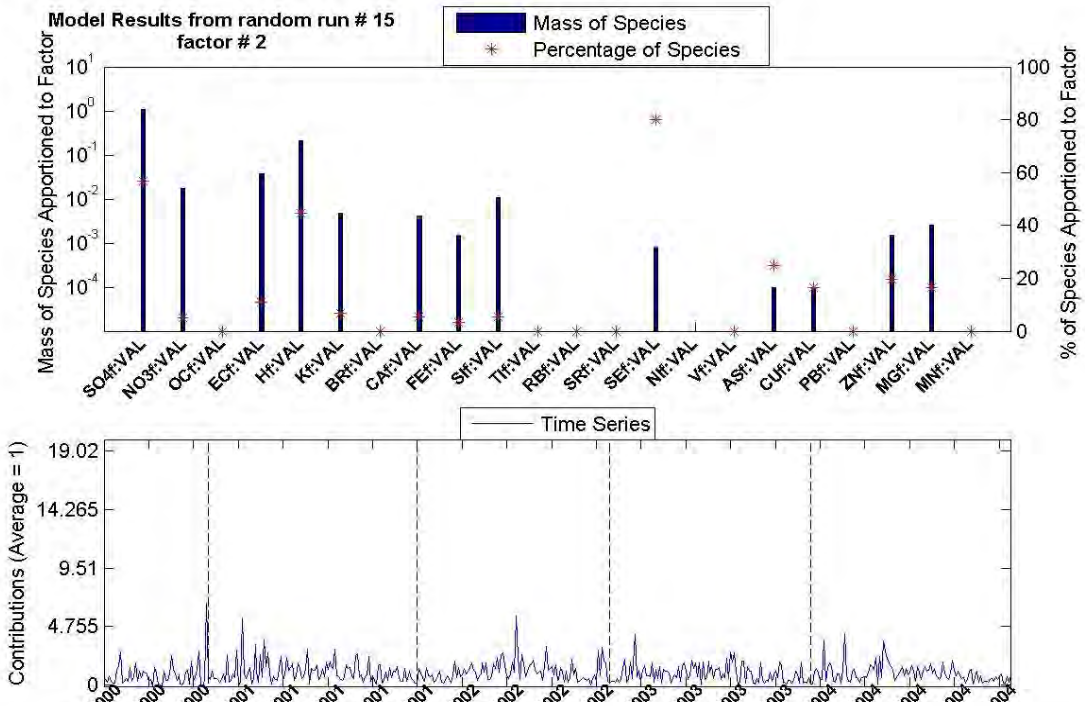




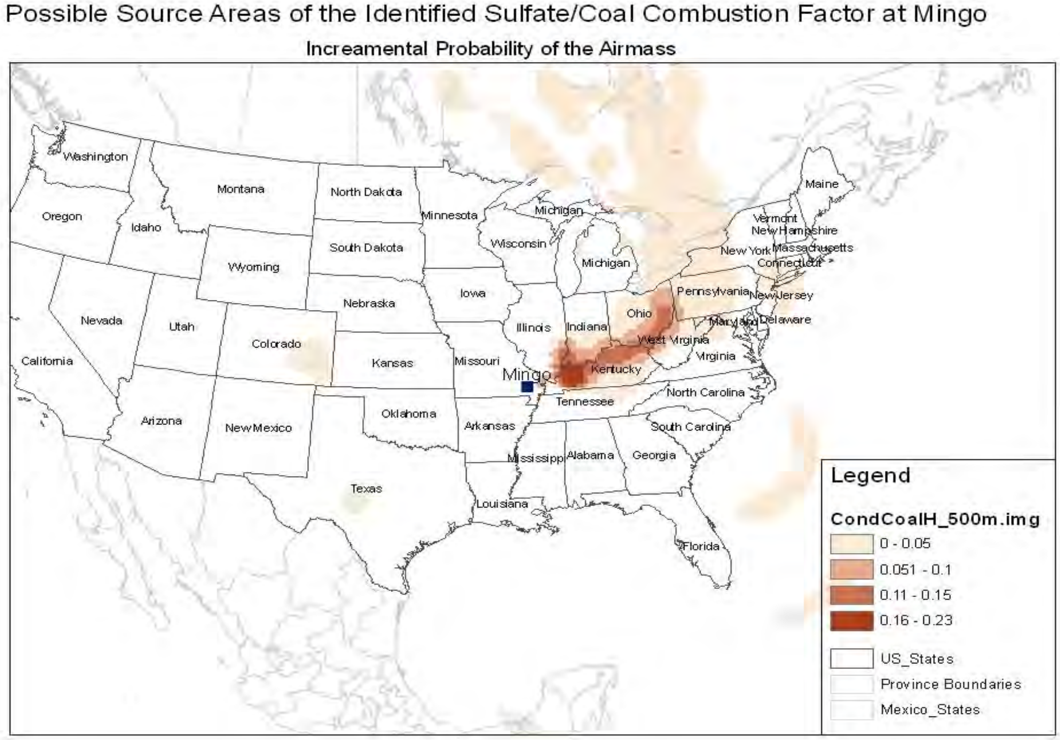


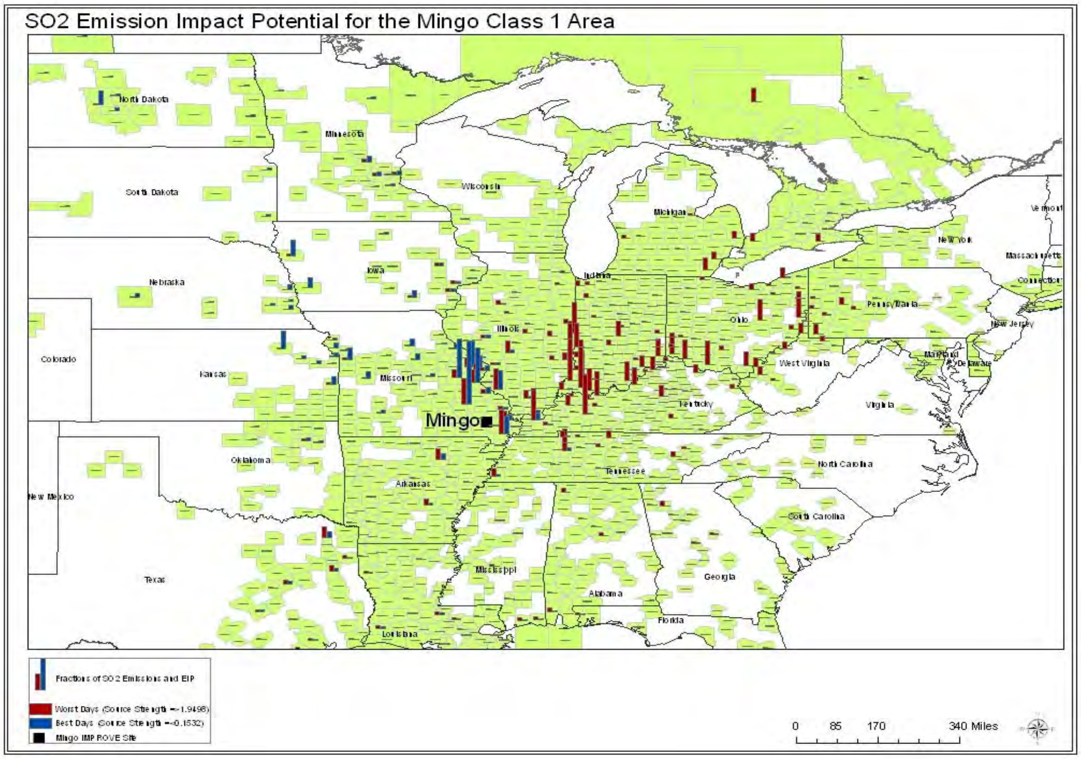
Monitoring Data Source Apportionment

The Coal Combustion Factor at the Mingo Class I Area

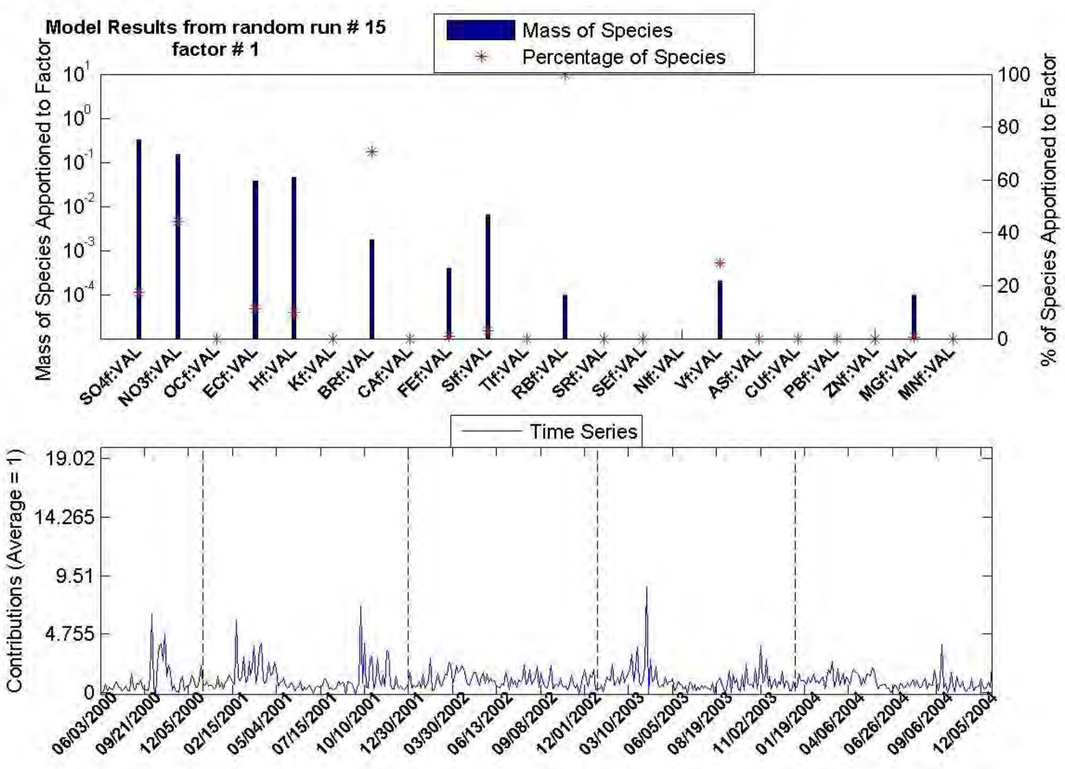


Possible Source Areas of the Identified Sulfate/Coal Combustion Factor at Mingo



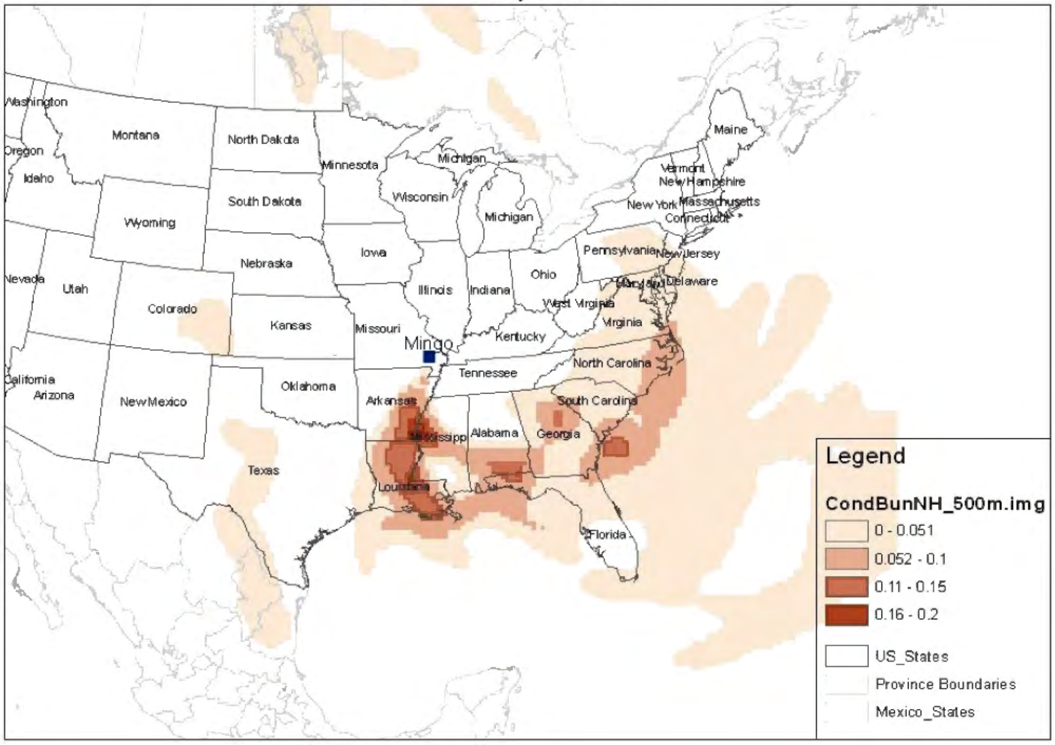


The Nitrate plus Spring Burning Factor at the Mingo Class I Area

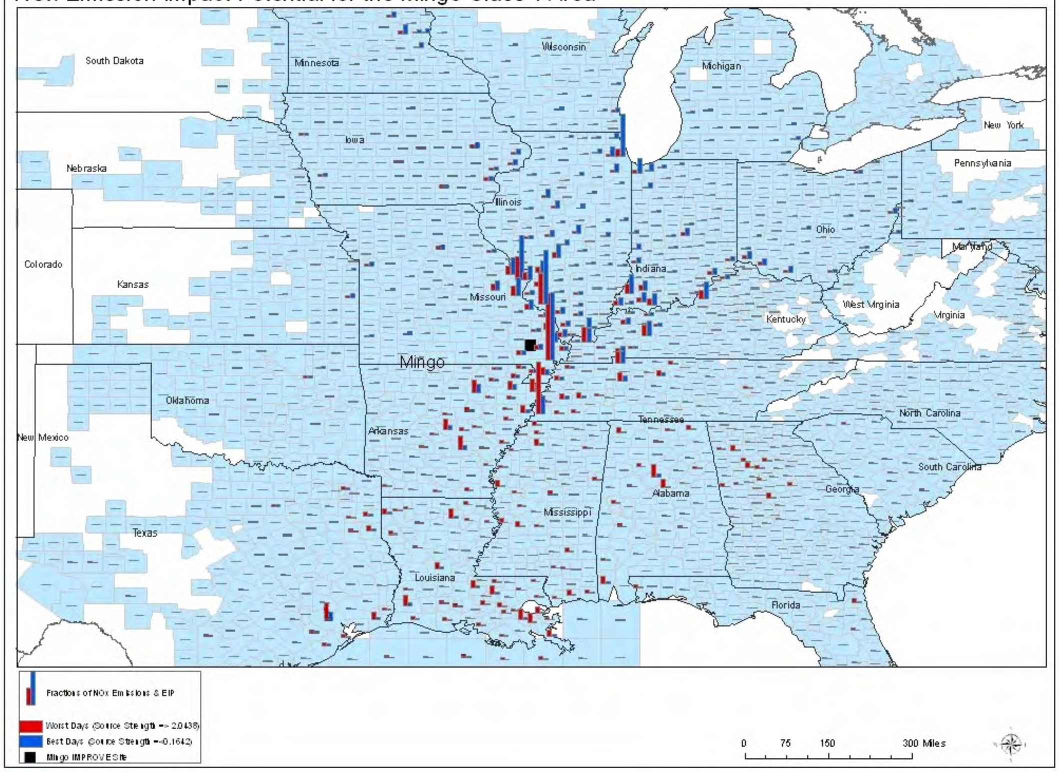


Possible Source Areas of the Identified Burning and Nitrate Factor at Mingo

Increamental Probability of the Airmass

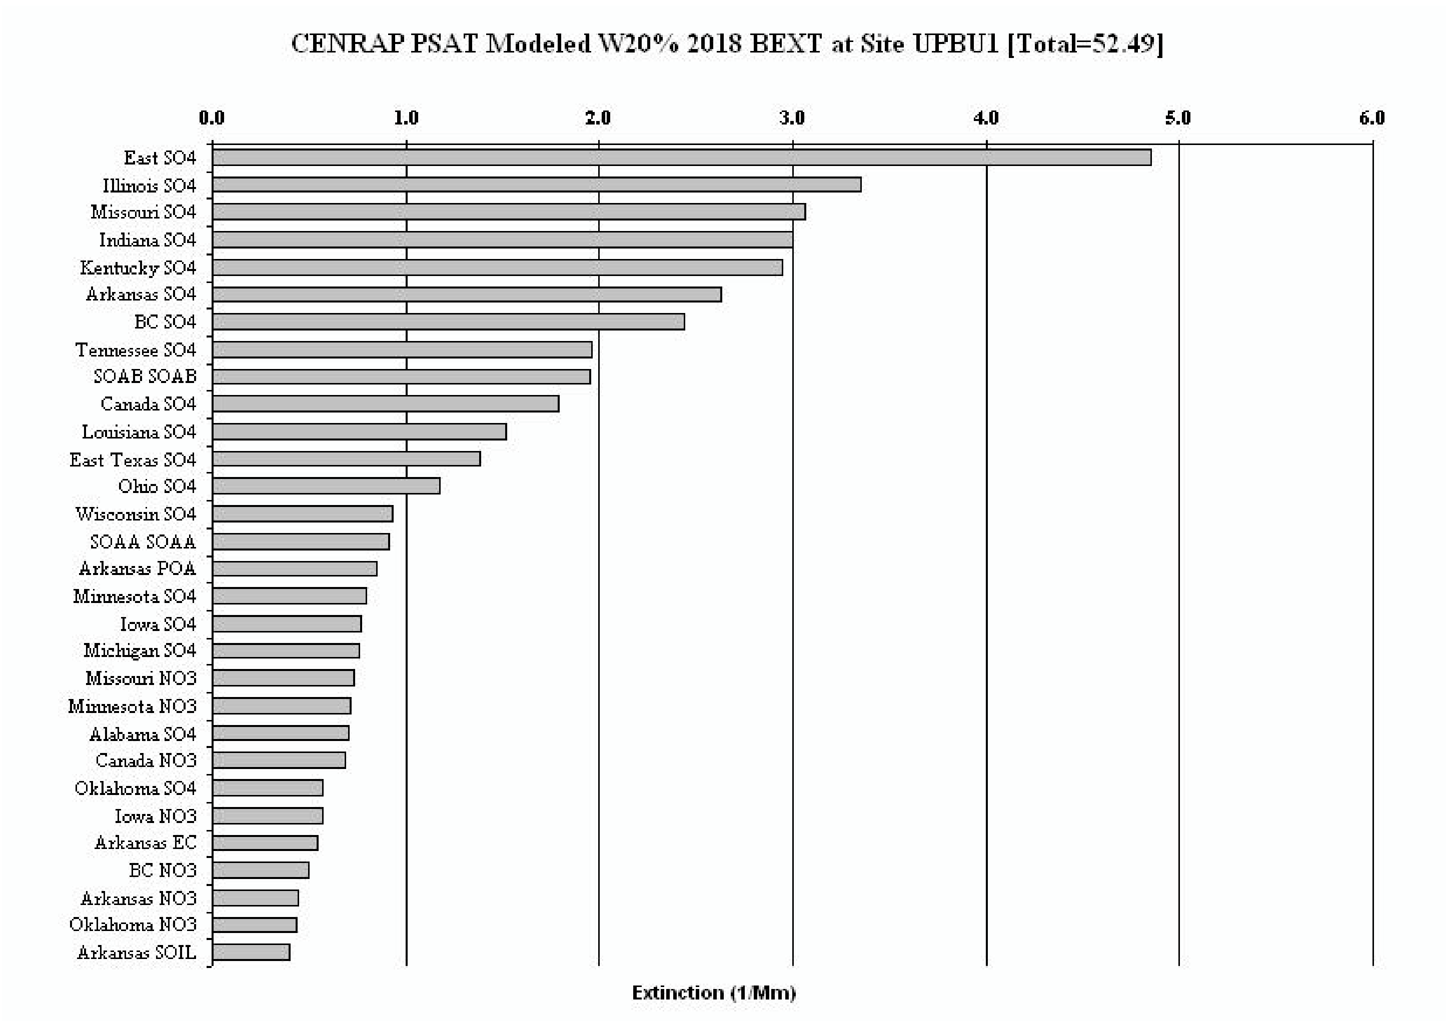


NOx Emission Impact Potential for the Mingo Class 1 Area

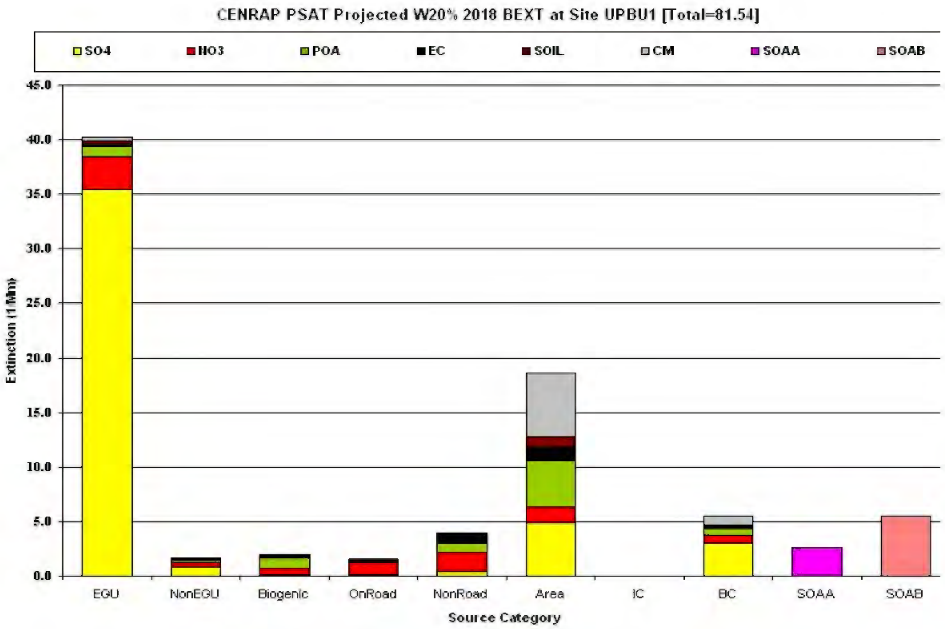


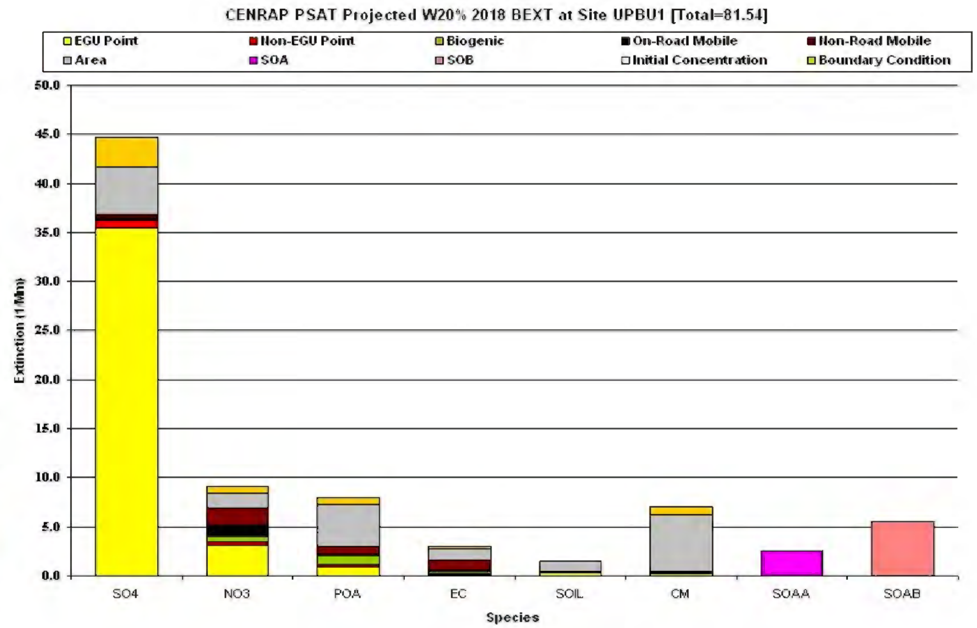
Source Apportionment for the Upper Buffalo Class I Area

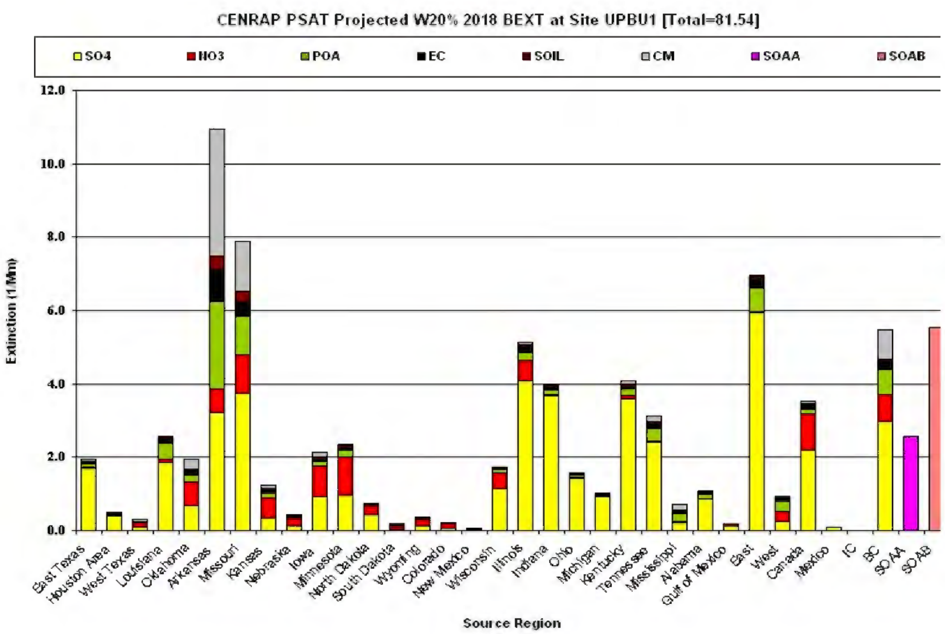
PSAT Model Source Apportionment

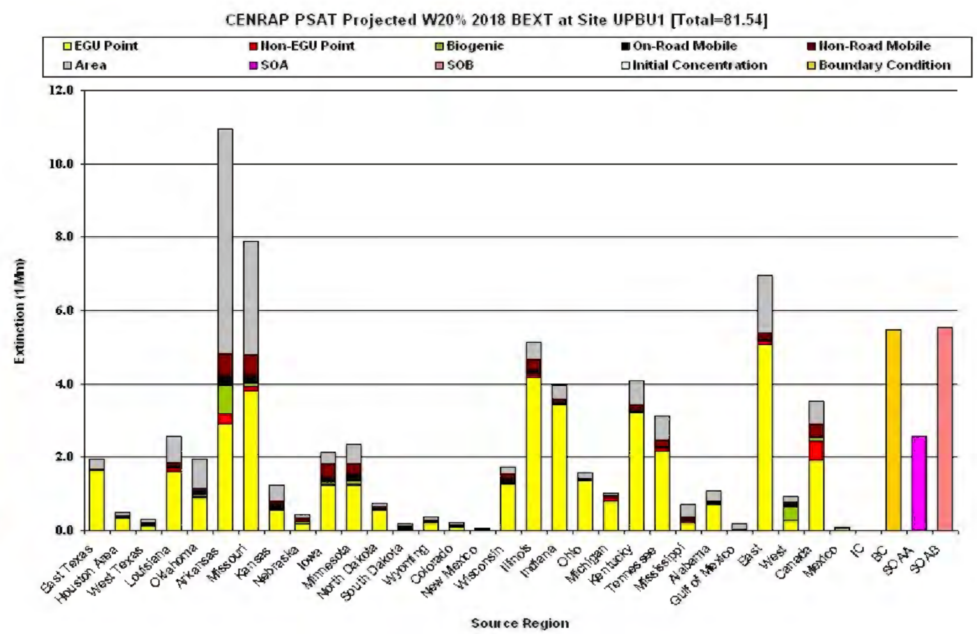


Upper Buffalo Projected 2018 – Worst 20%



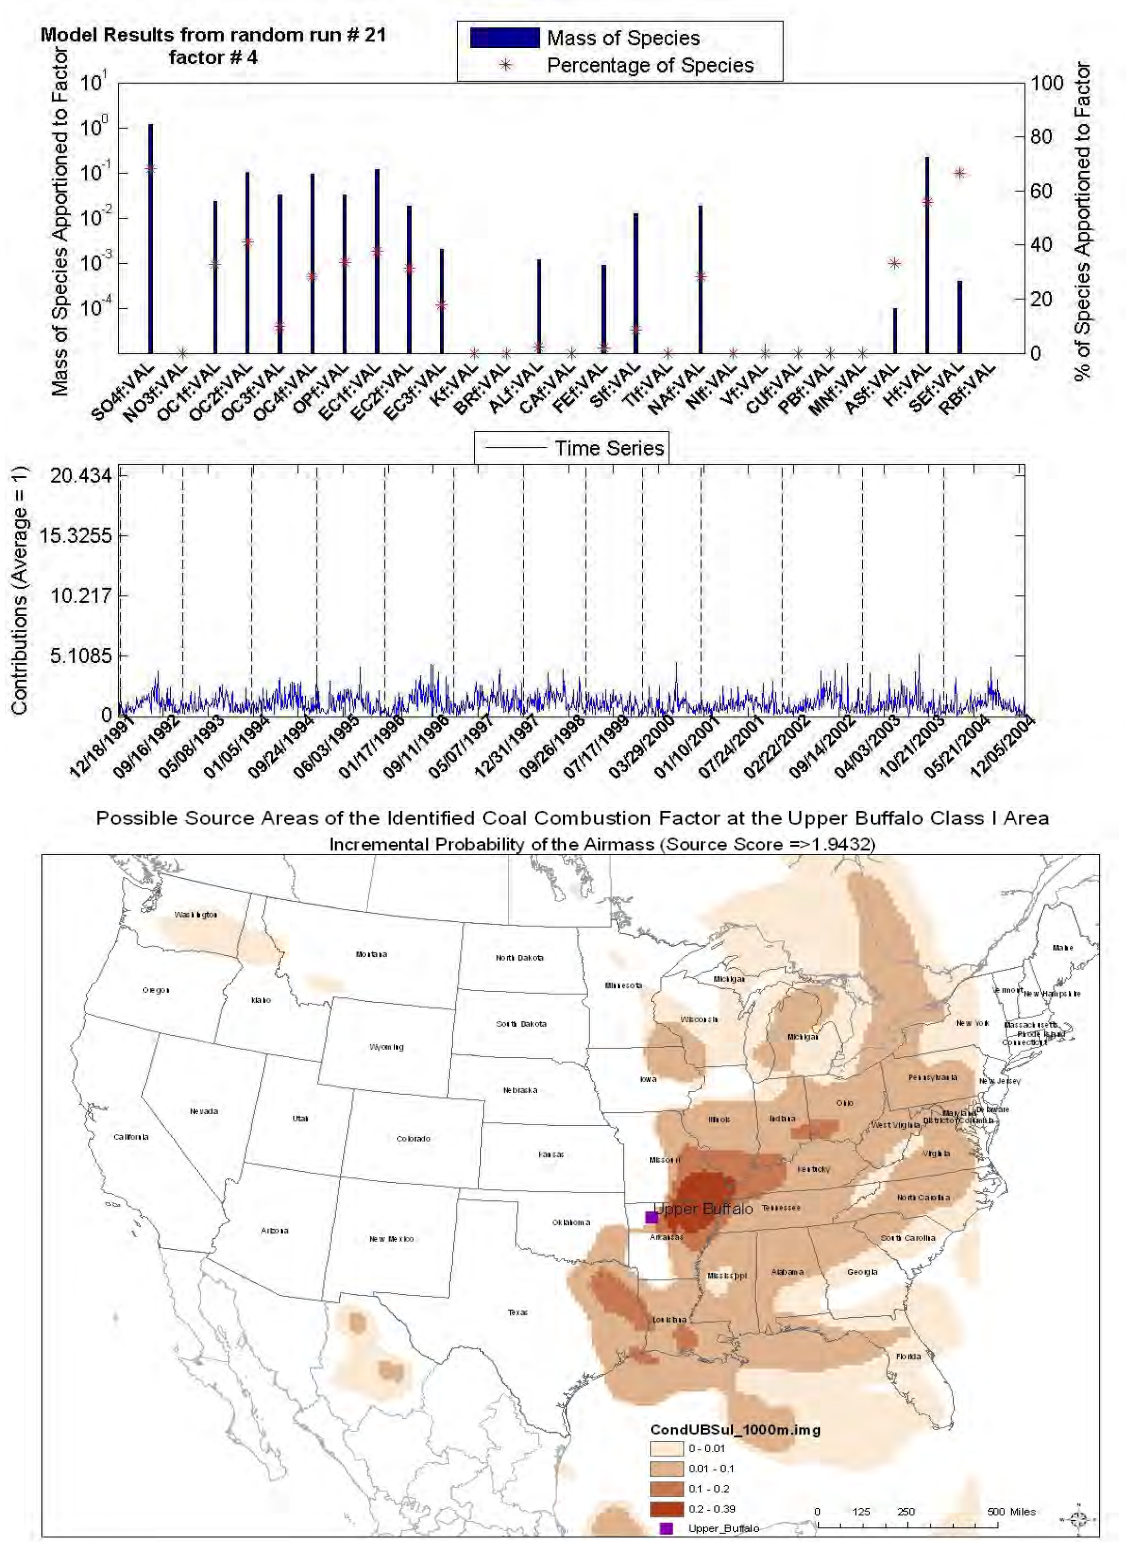


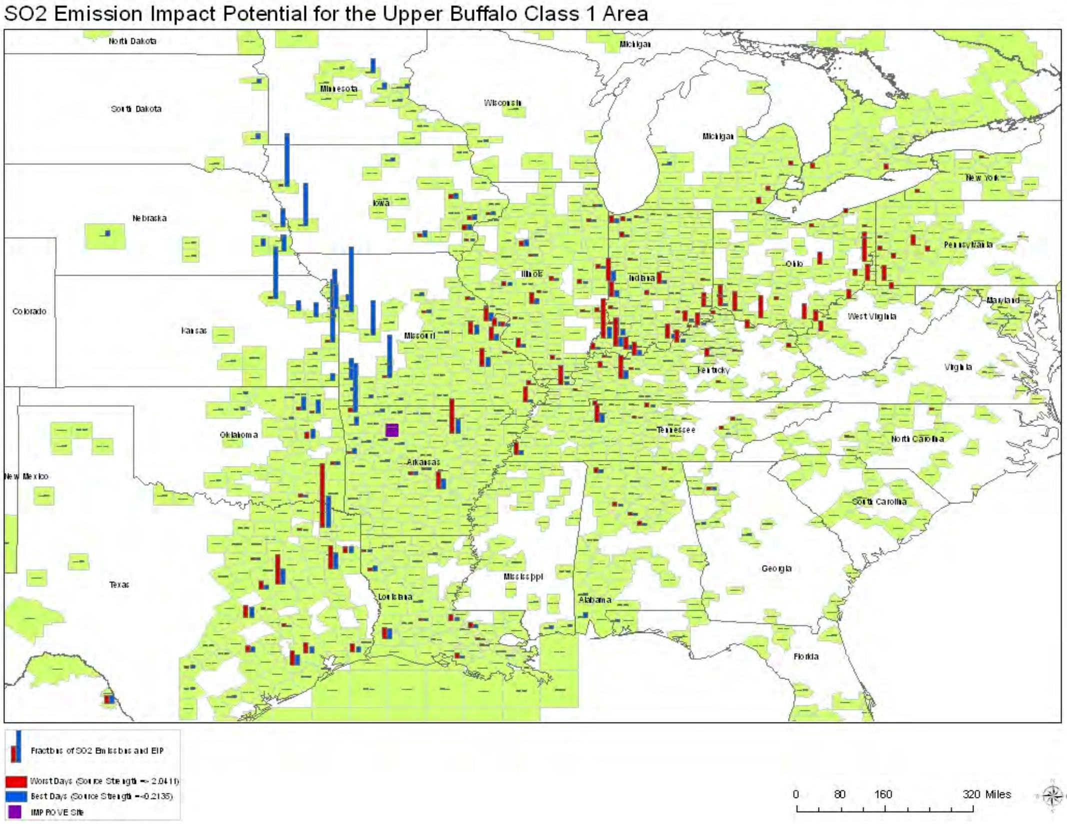




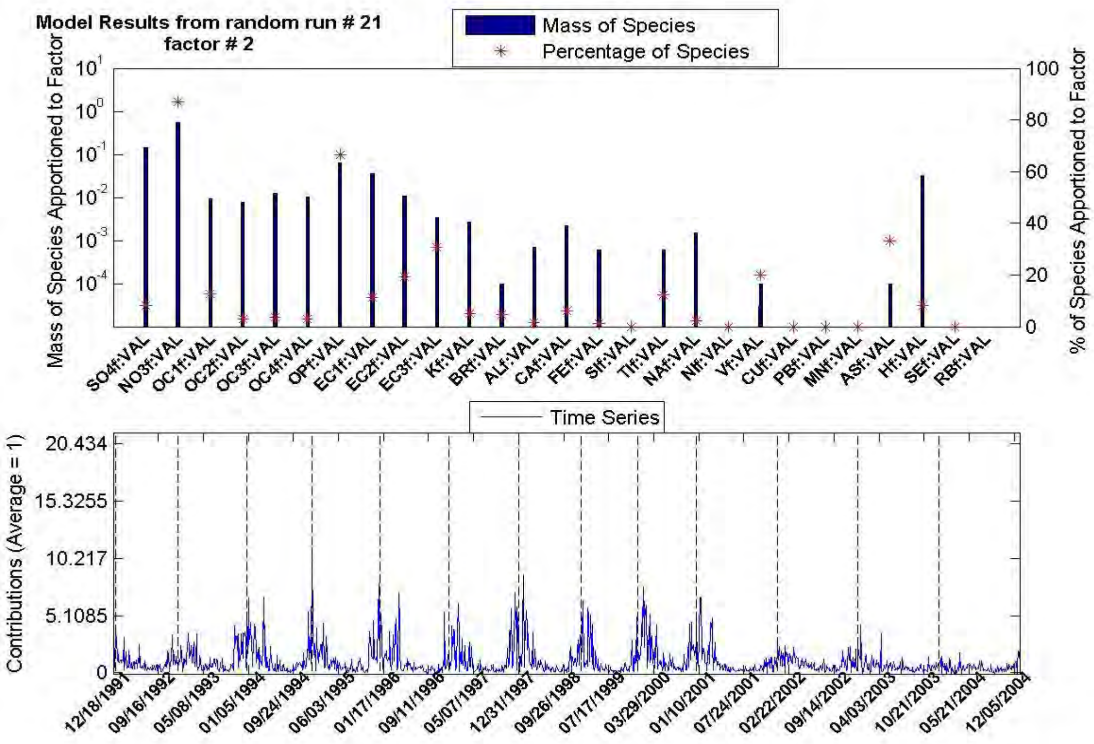
Monitoring Data Source Apportionment

The Coal Combustion Factor at the Upper Buffalo Class I Area



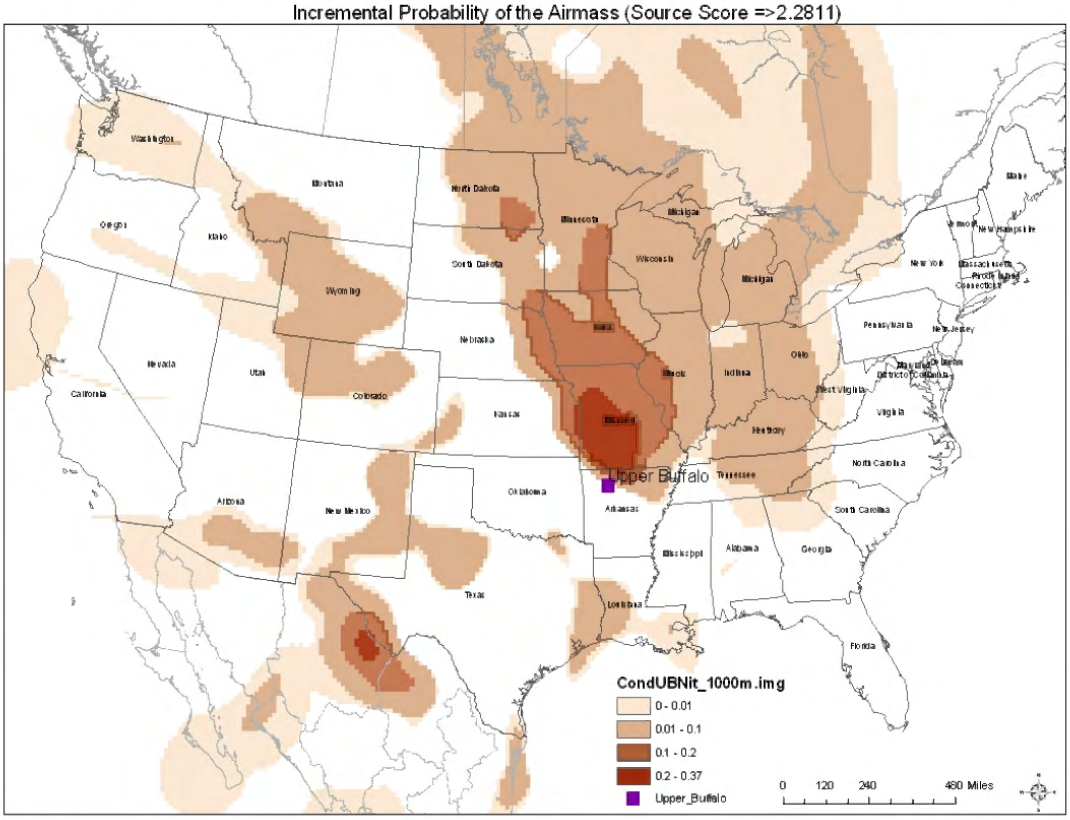


The Secondary Nitrate Factor at the Upper Buffalo Class I Area

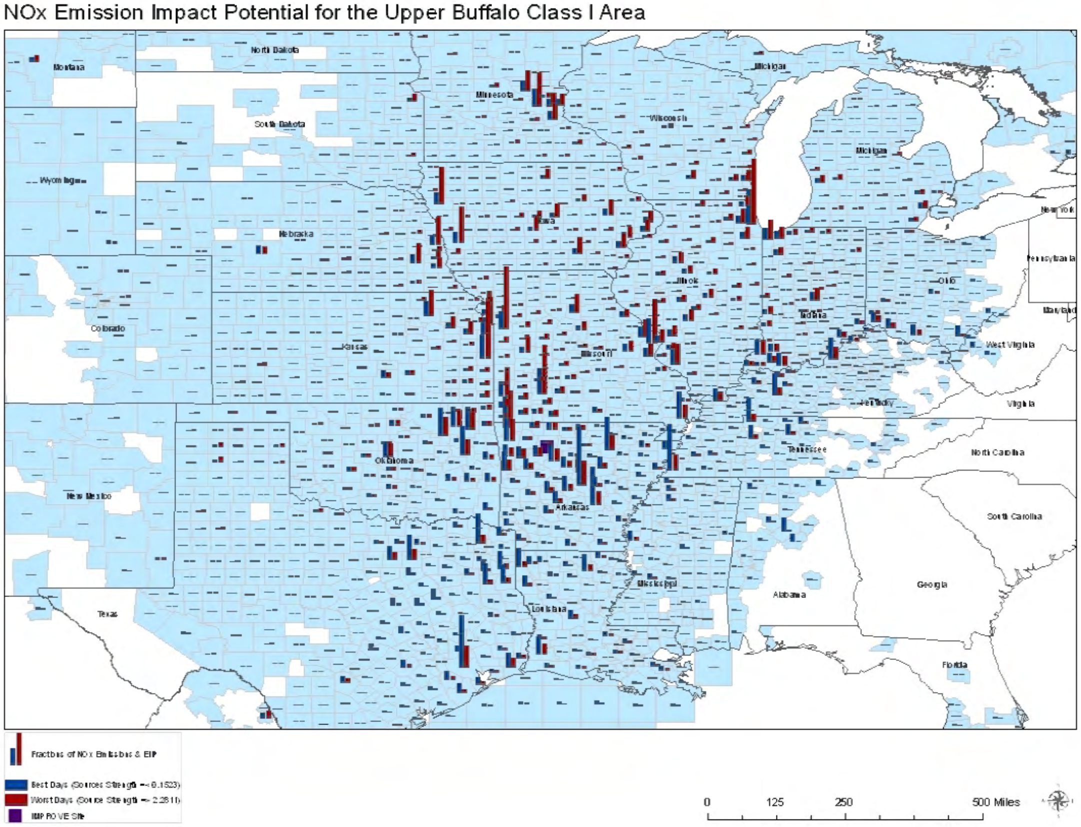


Possible Source Areas of the Identified Secondary Nitrate Factor at the Upper Buffalo Class I Area

Incremental Probability of the Airmass (Source Score =>2.2811)

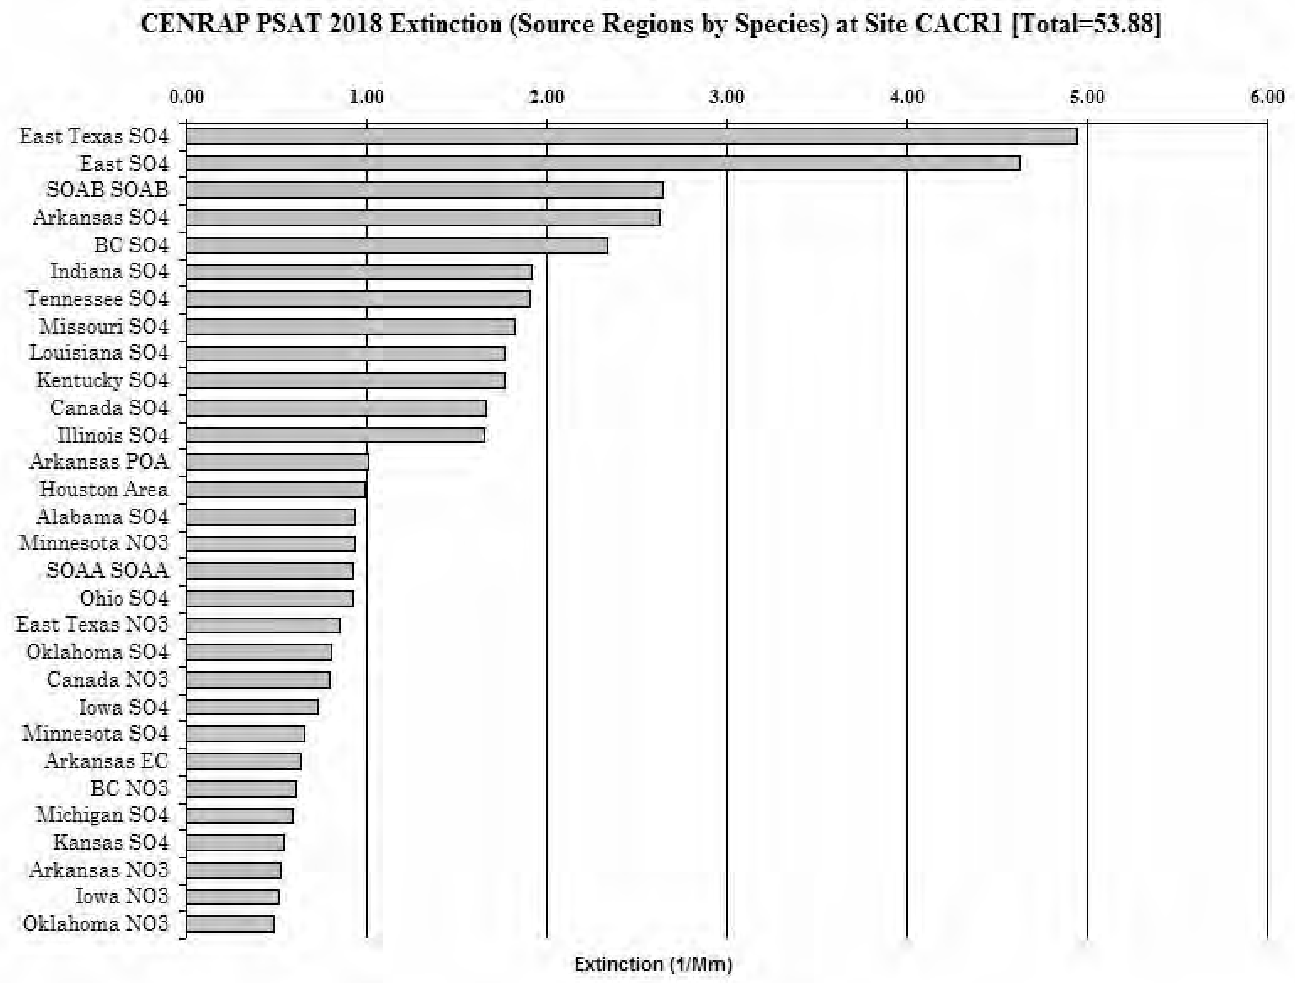


NOx Emission Impact Potential for the Upper Buffalo Class I Area

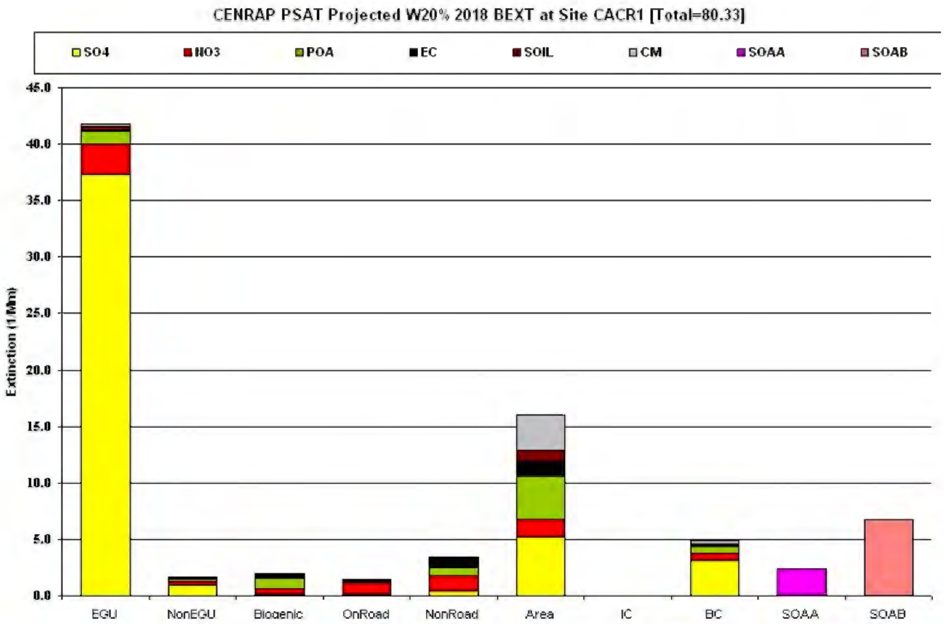


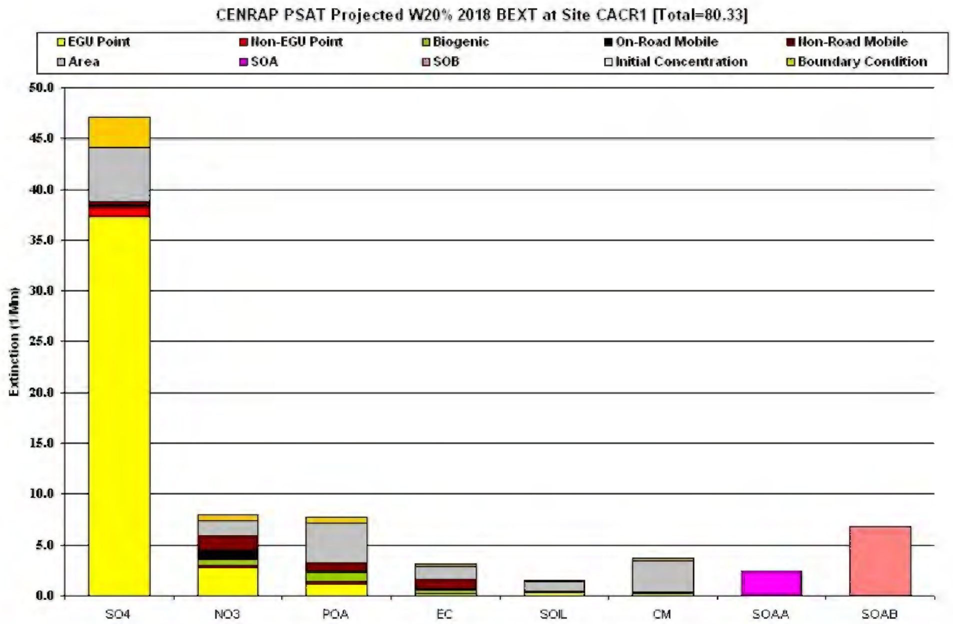
Source Apportionment for the Caney Creek Class I Area

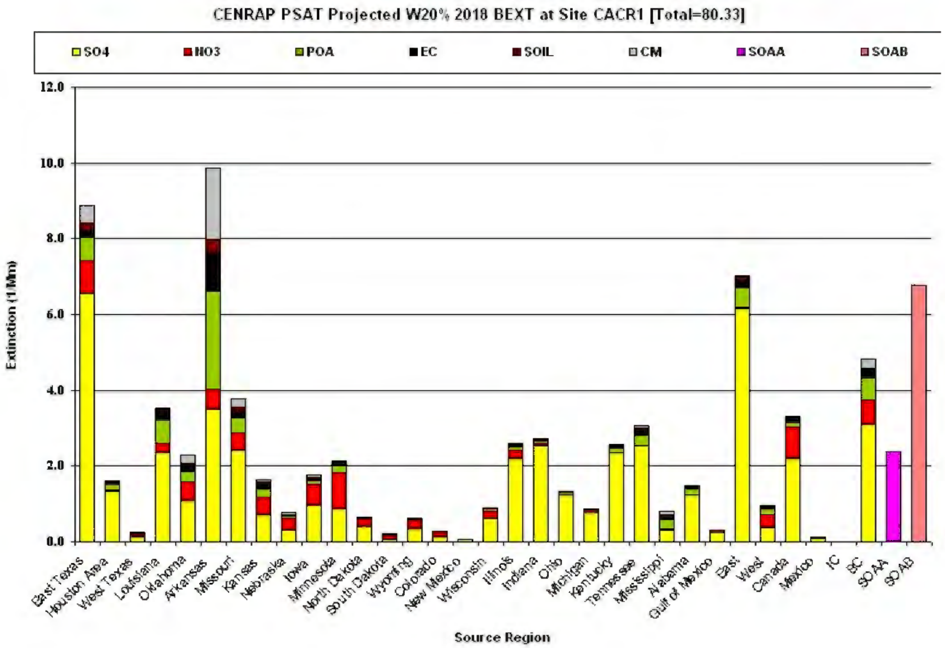
PSAT Model Source Apportionment

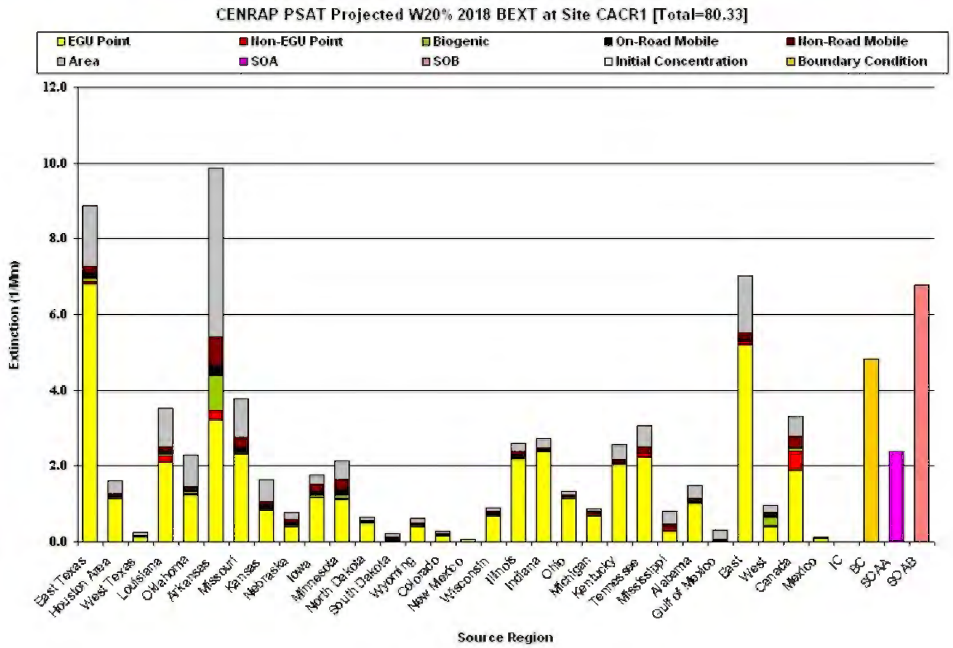


Caney Creek Projected 2018 – Worst 20%



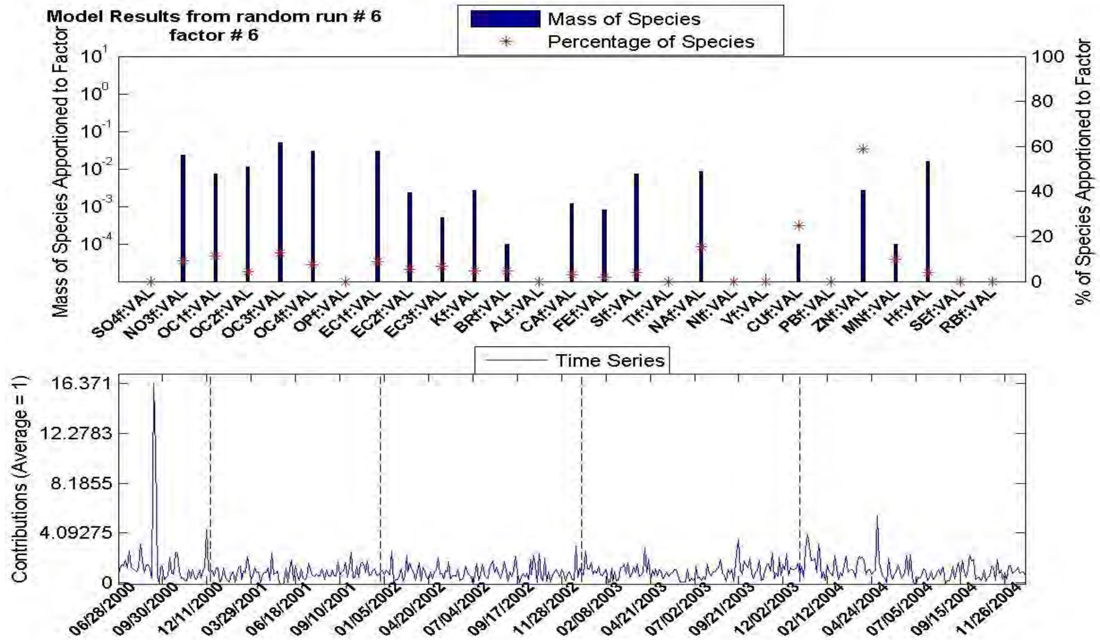


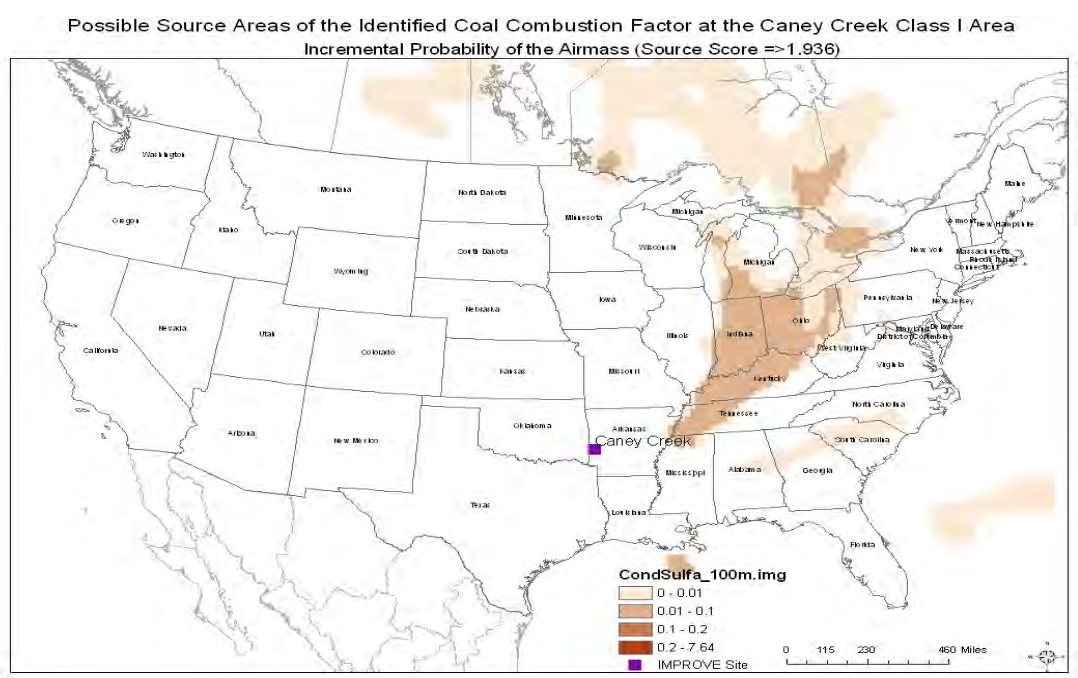


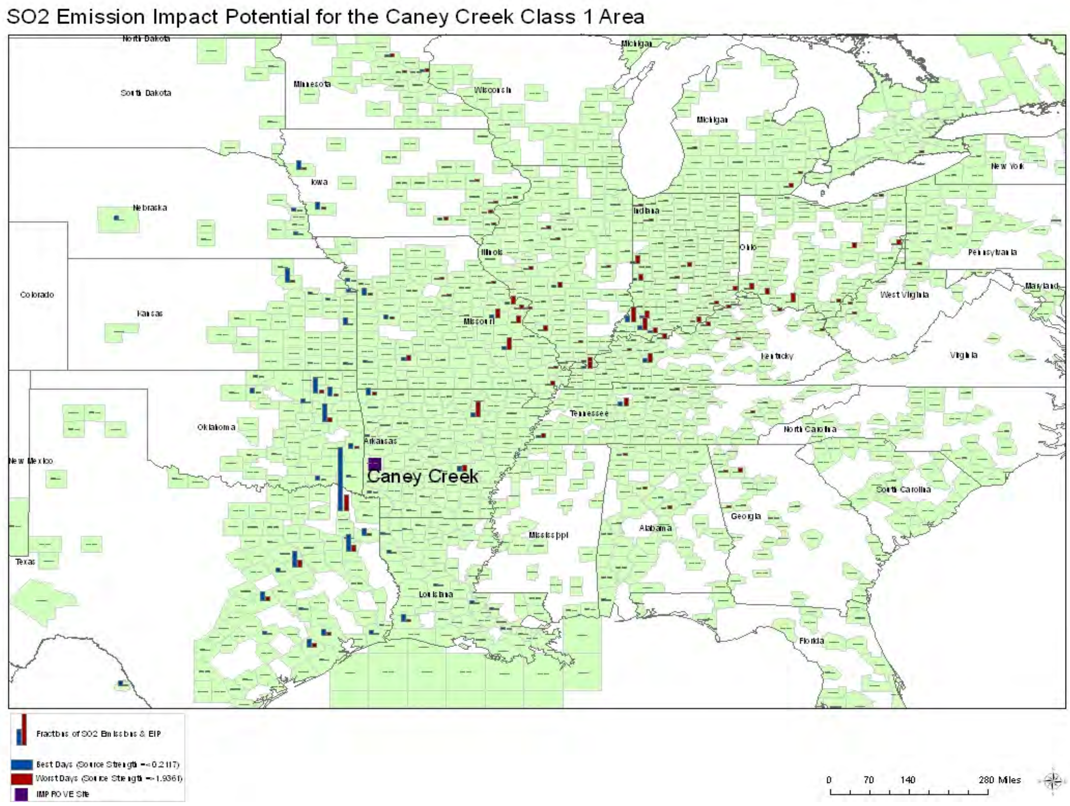


Monitoring Data Source Apportionment

The Coal Combustion Factor at the Caney Creek Class I Area







The Secondary Nitrate plus Oil Combustion Factor at the Caney Creek Class I Area

1.0 INTRODUCTION

This Technical Support Document (TSD) describes the Central Regional Air Planning Association (CENRAP) regional emissions and air quality modeling to support the central states Regional Haze Rule (RHR) State Implementation Plans (SIPs). The CENRAP 2002 annual emissions and air quality modeling was performed by the contractor team of ENVIRON International Corporation (ENVIRON) and the University of California at Riverside (UCR).

1.1 Background

The 1977 Clean Air Act Amendments (CAAA) added a new Section 169A for the protection of visibility in Federal Class I areas (specific national parks, wilderness areas and wildlife refuges). Section 169A(a)(1) of the CAAA established the national goal for visibility protection: "Congress hereby declares as a national goal the prevention of any future, and the remedying of any existing, impairment of visibility in mandatory class I Federal areas which impairment results from manmade air pollution." The CAAA require States to submit SIPs containing emission limits, schedules of compliance and to "promulgate regulations to assure reasonable progress toward meeting the national goal" (Section 169A(a)(4)). In response to these mandates EPA promulgated the Regional Haze Rule (RHR) on July 1, 1999 that requires States to "establish goals (expressed in deciviews) that provide for reasonable progress towards achieving natural visibility conditions" at Class I areas. The States' RHR SIPs are due December 17, 2007 and an important component of the SIP will be the 2018 Reasonable Progress Goals (RPGs) toward achieving natural conditions in 2064. Regional air quality models are used to project visibility to 2018 to determine the level of visibility improvement that is expected to be achieved in 2018. This information, along with other sources, can be used by the states to assist in setting their 2018 RPGs.

CENRAP is one of five Regional Planning Organizations (RPOs) that have responsibility for coordinating development of SIPs and Tribal Implementation Plans (TIPs) in selected areas of the U.S. to address the requirements of the RHR. CENRAP is a regional partnership of states, tribes, federal agencies, stakeholders and citizen groups established to initiate and coordinate activities associated with the management of regional haze and other air quality issues within the CENRAP states. The CENRAP region includes states and tribal lands located within the boundaries of Arkansas, Iowa, Kansas, Louisiana, Minnesota, Missouri, Nebraska, Oklahoma and Texas.

The CENRAP Emissions and Air Quality Modeling Team is composed of staff from ENVIRON and UCR, with assistance and coordination from the CENRAP states, tribes, federal agencies and stakeholders. The ENVIRON/UCR Team performs the emissions and air quality modeling simulations for states and tribes within the CENRAP region, providing analytical results used in developing implementation plans under the RHR. Figure 1-1 shows the states included in each of the five RPOs in the U.S., including CENRAP. Table 1-1 lists the Class I areas within the CENRAP states.

CENRAP is performing emissions and air quality modeling to project visibility to 2018. The modeling results will be used to determine the level of visibility improvement expected in 2018

under various emission scenarios. States will use these results to assist in determining their 2018 RPGs toward achieving natural conditions in 2064.

Figure 1-1. Regional Planning Organizations engaged in Regional Haze Modeling.

Table 1-1. Federal Mandated Class I Areas in the CENRAP States.

Class I Area	Acreage	Federal Land Manager	Public Law
Arkansas			
Caney Creek Wilderness Area	14,460	USDA-FS	93-622
Upper Buffalo Wilderness Area	12,018	USDA-FS	93-622
Louisiana			
Breton Wilderness Area	5,000+	USDI-FWS	93-632
Minnesota			
Boundary Waters Canoe Area Wilderness	810,088	USDA-FS	99-577
Voyageurs National Park	114,964	USDI-NP	99-261
Missouri			
Hercules-Glade Wilderness Area	12,314	USDA-FS	94-557
Mingo Wilderness Area	8,000	USDI-FWS	95-557
Oklahoma			
Wichita Mountains Wilderness	8,900	USDI-FWS	91-504
Texas			
Big Bend National Park	708,118	USDI-NP	74-157
Guadalupe Mountains National Park	76,292	USDI-NP	89-667

1.2 CENRAP Organizational Structure and Work Groups

The governing body of CENRAP is the Policy Oversight Group (POG) that is made up of voting members representing states and tribes within the CENRAP region and non-voting members representing local agencies, the EPA and other federal agencies. The work of CENRAP is accomplished through five standing workgroups:

- Monitoring;
- Emissions Inventory;
- Modeling;
- Communications; and
- Implementation and Control Strategies.

Participation in workgroups is open to all interested parties and the POG may form additional ad hoc workgroups to address specific issues (e.g., a Data Analysis workgroup was formed).

The RHR requires the states, and the tribes that may elect to, submit the first SIPs and TIPs that address progress toward natural conditions at federally mandated Class I areas by December 17, 2007. 40 CFR 51.308 (Section 308) discusses the following four core requirements to be included in SIPs/TIPs and Best Available Retrofit Technology (BART) requirements:

1. Reasonable progress goals;
2. Calculations of baseline and natural visibility conditions;
3. A Long-term strategy for regional haze;
4. A Monitoring strategy and other implementation plan requirements; and
5. BART requirements for regional haze visibility impairment.

One of CENRAP's goals is to provide support to states and tribes to meet each of these requirements of the RHR and to develop scientifically supportable, economical and effective control strategies that the states and tribes may adopt to reduce anthropogenic effects on visibility impairment at Class I areas. One component of CENRAP's support to states and tribes as part of compliance with the RHR is performing emissions and air quality modeling. These activities were implemented to:

- obtain a better understanding of the causes of visibility impairment and to identify potential mitigation measures for visibility impairment at Class I areas;
- to evaluate the effects of alternative control strategies for improving visibility; and
- to project future-year air quality and visibility conditions.

In October 2004, CENRAP selected the team of ENVIRON and UCR to perform their Emissions and Air Quality Modeling.

The CENRAP Emissions and Air Quality Modeling Team performs regional haze analyses by operating regional scale, three-dimensional air quality models that simulate the emissions, chemical transformations, and transport of gaseous and particulate matter (PM) species and consequently the effects on visibility in Class I Areas in the central U.S. A key element of this work includes the integration of emissions inventories and emissions models with regional transport models. The general services provided by the CENRAP Emissions and Air Quality Modeling Team include, but are not limited to:

- Emissions processing and modeling;
- Air quality and visibility modeling simulations;
- Analysis, display, and reporting of modeling results; and
- Storage/quality assurance of the modeling input and output files.

The CENRAP 2002 annual Emissions and Air Quality Modeling Team performs work for the CENRAP Modeling Workgroup through direction from the CENRAP Technical Director and CENRAP Executive Director.

1.3 Overview of 2002 Annual Emissions and Air Quality Modeling Approach

The CENRAP 2002 annual emissions and air quality modeling was initiated on October 16, 2004 and involved the preparation of numerous databases, model simulations, presentations and reports. Much of the modeling analyses have been posted to the CENRAP modeling website at: http://pah.cert.ucr.edu/aqm/cenrap/index.shtml. There were numerous versions and iterations of the modeling and interim results. The results presented in this TSD focus on the final modeling results and key findings in their development. The reader is referred to the modeling website for interim products.

1.3.1 Modeling Protocol

A Modeling Protocol was prepared at the outset of the study to serve as a road map for performing the CENRAP emissions and air quality modeling and to communicate the modeling

plans to the CENRAP participants. The Modeling Protocol was prepared following EPA guidance for preparation at the time it was prepared (EPA, 1991; 1999, 2001) and took into account CENRAP's long-term plan (CENRAP, 2003) and the modeling needs of the RHR SIPs. The first version (Version 1.0) of the Modeling Protocol was dated November 19, 2004. Based on comments received from CENRAP, the Modeling Protocol was updated to the current Version 2.0 (Morris et al., 2004a) that was dated December 8, 2004. This Modeling Protocol can be found on the CENRAP modeling Website at:

http://pah.cert.ucr.edu/aqm/cenrap/docs/CENRAP_Draft2.0_Modeling_Protocol_120804.pdf

1.3.2 Quality Assurance Project Plan (QAPP)

A Quality Assurance Project Plan (QAPP) was prepared for the CENRAP emissions and air quality modeling study that described the quality management functions performed by the modeling team. The QAPP was prepared and was based on the national consensus standards for quality assurance (ANSI/ASQC, 1994), followed EPA's guidelines for quality assurance project plans for modeling (EPA, 2002) and for QAPPs (EPA, 2001) and took into account the recommendations from the North American Research Strategy for Tropospheric Ozone (NARSTO) Quality Handbook for modeling projects (NARSTO, 1998). The EPA and NARSTO guidance documents were developed specifically for modeling projects, which have different quality assurance concerns than environmental monitoring data collection projects. The work performed in this project involves modeling at the basic research level and for regulatory/planning applications. In order to use model outputs for these purposes, it must be established that each model is scientifically sound, robust, and defensible. This is accomplished by following a project planning process that incorporates the following elements as described in the EPA modeling guidance document:

- A systematic planning process including identification of assessments and related performance criteria;
- Peer reviewed theory and equations;
- A carefully designed life-cycle development process that minimizes errors;
- Documentation of any changes from original plans;
- Clear documentation of assumptions, theory, and parameterization that is detailed enough so others can understand the model output;
- Input data and parameters that are accurate and appropriate for the analysis; and
- Output data that can be used to help inform decision makers.

The CENRAP QAPP can be found at:

http://pah.cert.ucr.edu/aqm/cenrap/docs/CENRAP_QAPP_Nov_24_2004.pdf).

A key component of the CENRAP emissions and air quality modeling QAPP was the graphical display of model inputs and outputs and multiple peer-review of each step of the modeling process. This was accomplished through use of the CENRAP modeling website where modelers posted displays of work products (e.g., emissions plots, model outputs, etc.) for review by the CENRAP modeling team, modeling workgroup and others. This website can be found at: http://pah.cert.ucr.edu/aqm/cenrap/index.shtml.

1.3.3 Model Selection

The selection of the meteorological, emissions and air quality models for the CENRAP regional haze modeling was based on a review of previous regional haze modeling studies performed in the CENRAP region (e.g., Pitchford et al., 2004; Pun, Chen and Seigneur, 2004; Tonnesen and Morris 2004) as well as elsewhere in the United States (e.g., Morris et al, 2004a; Tonnesen et al., 2003; Baker, 2004). The CENRAP emissions and air quality Modeling Protocol (Morris et al., 2004a) provides details on the justification for model selection and the formulation of the different models. Based on previous work (e.g., CENRAP, WRAP, VISTAS, MRPO, BRAVO and EPA), CENRAP selected the following models for use in modeling PM and regional haze in the central states:

- **MM5:** The Pennsylvania State University/National Center for Atmospheric Research (PSU/NCAR) Mesoscale Meteorological Model (MM5 Version 3.6 MPP) is a non-hydrostatic, prognostic meteorological model routinely used for urban- and regional-scale photochemical, fine particulate, and regional haze regulatory modeling studies (Anthes and Warner, 1978; Chen and Dudhia, 2001; Stauffer and Seaman, 1990, 1991; Xiu and Pleim, 2000).

- **SMOKE**: The Sparse Matrix Operator Kernel Emissions (SMOKE) modeling system is an emissions modeling system that generates hourly gridded speciated emission inputs of mobile, non-road, area, point, fire and biogenic emission sources for photochemical grid models. (Coats, 1995; Houyoux and Vukovich, 1999). As with most ‘emissions models’, SMOKE is principally an *emission processing system* and not a true *emissions modeling system* in which emissions estimates are simulated from ‘first principles’. This means that, with the exception of mobile and biogenic sources, its purpose is to provide an efficient tool for converting an existing base emissions inventory data into the hourly, gridded, speciated, and formatted emission files required by an air quality model.

- **CMAQ:** EPA’s Models-3/Community Multiscale Air Quality (CMAQ) modeling system is a ‘One-Atmosphere’ photochemical grid model capable of addressing ozone, PM, visibility and acid deposition at a regional scale for extended periods of time (Dennis, et al., 1996; Byun et al., 1998a; Byun and Ching, 1999, Pleim et al., 2003).

- **CAMx:** ENVIRON’s Comprehensive Air Quality Model with Extensions (CAMx) modeling system is also a state-of-science ‘One-Atmosphere’ photochemical grid model capable of addressing ozone, PM, visibility and acid deposition at a regional scale for extended periods of time. (ENVIRON, 2006).

1.3.3.1 MM5 Meteorological Model Configuration for CENRAP Annual Modeling

Application of the MM5 for the 2002 annual modeling on a 36 km grid for the continental US was performed by the Iowa Department of Natural Resources (IDNR; Johnson, 2007). Details of the 2002 36 km MM5 model application and evaluation procedures carried out by IDNR may be found in Johnson, 2007. Application of the MM5 model on a 12 km grid covering the Central States for portions of 2002 was performed by EPA Region VII and the Texas Commission on Environmental Quality (TCEQ).

The MM5 (Version 3.63) configuration used in the generation of the meteorological modeling datasets consists of the following (see Table 1-2 for more details):

- 36 km grid with 34 vertical layers;
- 12 km nested grid for episodic modeling;
- For 12 km runs use two way nesting (without feedback) within the 36 km grid;
- Initialization and boundary conditions from Eta analysis fields;
  - Eta 3D and surface analysis data (ds609.2);
  - Not using NCEP global tropospheric SST data (ds083.0) ;
  - Observational enhancement (LITTLE_R)
    - NCEP ADP surface obs (ds464.0)
    - NCEP ADP upper-air obs (ds353.4)
- Pleim-Xiu (P-X) land-surface model (LSM);
- Pleim-Chang Asymmetric Convective Mixing (ACM) PBL model;
- Kain-Fritsch 2 cumulus parameterization;
- Mixed phase (Reisner 1) cloud microphysics;
- Rapid Radiative Transfer Model (RRTM) radiation;
- No Shallow Convection (ISHALLO=0);
- Standard 3D FDDA analysis nudging outside of PBL; and
- Surface nudging of the winds only.

1.3.3.2 SMOKE Emissions Model Configuration for CENRAP Annual Modeling

SMOKE supports area, mobile, fire and point source emission processing and includes biogenic emissions modeling through a rewrite of the Biogenic Emission Inventory System, version 3 (BEIS3) (see, http://www.epa.gov/ttn/chief/software.html#pcbeis). SMOKE has been available since 1996, and has been used for emissions processing in a number of regional air quality modeling applications. In 1998 and 1999, SMOKE was redesigned and improved with the support of the U.S. Environmental Protection Agency (EPA), for use with EPA's Models-3/CMAQ (http://www.epa.gov/asmdnerl/models3). The primary purposes of the SMOKE redesign were support of: (a) emissions processing with user-selected chemical mechanisms and (b) emissions processing for reactivity assessments.

As an emissions processing system, SMOKE has far fewer ‘science configuration’ options compared with the MM5 and CMAQ models. Table 1-3 summarizes the version of the SMOKE system that was used and the sources of data that were employed in constructing the required modeling inventories.

1.3.3.3 CMAQ Air Quality Model Configuration for CENRAP Annual Modeling

CENRAP used CMAQ Version 4.5 with the “SOAmods enhancement”, described below, and used the model configuration as shown in Table 1-4. The model was set up and exercised on the same 36 km grid that was used by WRAP and VISTAS, the 36 km RPO national grid. CENRAP performed 12 km CMAQ sensitivity tests and found little change in model performance with a large penalty in computation time. Consequently, at the February 7, 2006 CENRAP Modeling

Workgroup Meeting a decision was made to proceed with the CENRAP emissions and air quality modeling using just the 36 km national RPO grid (Morris et al., 2006a).

Initial CMAQ 2002 simulations performed by VISTAS found that the model greatly underestimates organic mass carbon (OMC) concentrations, especially in the summer. A review of the CMAQ formulation found that it failed to treat Secondary Organic Aerosol (SOA) formation from sesquiterpenes and isoprene and also failed to account for the fact that SOA can become polymerized so that it is no longer volatile and stays in the particle form. Thus, VISTAS updated the CMAQ SOA module to include these missing processes and found much improved OMC model performance (Morris et al., 2006c). CENRAP tested the CMAQ Version 4.5 with SOAmods enhancement and found it performed much better for OMC than the standard versions of CMAQ Version 4.5. Therefore, CMAQ Version 4.5, with the enhanced SOAmods (Morris et al., 2006c), was adopted for the CENRAP modeling. CMAQ Version 4.5 is available from the CMAS center (www.cmascenter.org).

1.3.3.4 CAMx Air Quality Model Configuration for CENRAP Annual Modeling

CAMx Version 4.40 was applied using similar options as used by CMAQ. CAMx was used initially in side-by-side comparisons with CMAQ. Comparative model performance results and other factors for CAMx V4 and CMAQ V4.4 with SOAmods were presented at the February 7, 2006 CENRAP modeling workgroup meetings that found (Morris et al., 2006b):

- No one model was consistently performing better than the other over all species and averaging times.
- Both models performed well for sulfate.
- CMAQ's winter nitrate over-prediction tendency not as large as CAMx's.
- CAMx performed slightly better than CMAQ for elemental carbon (EC).
- CMAQ performed much better than CAMx for organic mass carbon (OMC).
- Both models over-predicted Soil and under-predicted coarse mass (CM).
- CMAQ ran faster than CAMx due to MPI multi-processing capability.
- CAMx required much less disk space than CMAQ.

Based on these factors, CMAQ was selected as the lead air quality model for the CENRAP regional haze modeling with CAMx the secondary corroborative model. However, CAMx also contained a PM Source Apportionment Technology (PSAT) capability that was used widely in the CENRAP modeling. Table 1-4 lists the main CAMx configuration used for the CENRAP annual modeling that was selected, in part, to be consistent with the CMAQ model configuration (Table 1-4). One exception to this was that the CAMx PSAT simulations used the Bott advection solver rather than the PPM advection solver. The PPM advection solver is typically used in the standard CAMx and CMAQ runs. Bott, however, is more computationally efficient and the high computational requirements of the CAMx PSAT runs dictated this choice.

Table 1-2. MM5 Meteorological Model Configuration for CENRAP 2002 Annual Modeling (Johnson, 2007).

Science Options	Configuration	Details/Comments
Model Code	MM5 version 3.63	Grell et al., 1994
Horizontal Grid Mesh	36 km	
36 km grid	165 x 129 dot points	RPO MM5 Grid
Vertical Grid Mesh	34 layers	Vertically varying; sigma pressure coordinate system
Grid Interaction	No Feedback	IFEED=0
Initialization	Eta first guess fields/LittleR	
Boundary Conditions	Eta first guess fields/LittleR	
Microphysics	Reisner I Mixed Ice	Look up table
Cumulus Scheme	Kain-Fritsch 2	On 36 and 12 km Grids
Planetary Boundary Layer	ACM PBL	
Radiation	RRTM	
Vegetation Data	USGS	24 Category Scheme
Land Surface Model	Pleim-Xiu Land Surface Model (LSM)	
Shallow Convection	None	
Sea Surface Temperature	Eta Skin	Spatially varying
Thermal Roughness	Garratt	
Snow Cover Effects	None	
4D Data Assimilation	Analysis Nudging on 36 and 12	
Surface Nudging	Wind Field Only	
Integration Time Step	90 seconds	
Simulation Periods	Annual 2002 for 36 km	12 km episodic only
Platform	Linux Cluster	Done at IDNR[1]

Integration Time Step	Wind speed dependent	

1.3.4 Modeling Domains

The CENRAP emissions and air quality modeling was conducted on the 36 km national RPO domain as depicted in Figure 1-2. This domain consists of a 148 by 112 array of 36 km by 36 km grid cells and covers the continental United States. Sensitivity simulations were also performed for episodes on a 12 km modeling domain covering the central states, however the results were very similar to the 36 km results so CENRAP elected to proceed with the 2002 annual modeling using the 36 km domain for computational efficiency (Morris et al., 2006a).

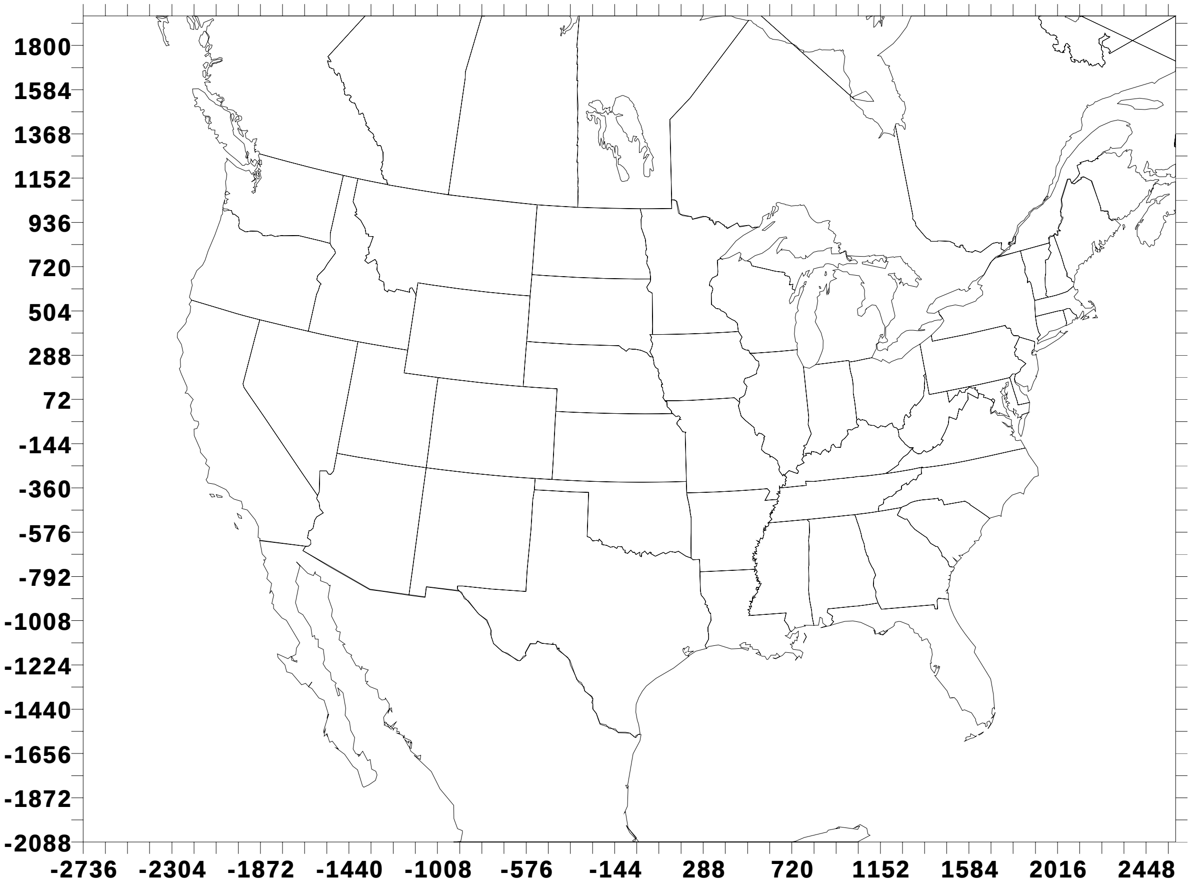

Figure 1-2. National Inter-RPO 36 km modeling domain used for the CENRAP 2002 annual SMOKE, CMAQ and CAMx modeling.

1.3.5 Vertical Structure of Modeling Domain

The MM5 meteorological model was exercised using 34 vertical layers from the surface to a pressure level of 100 mb (approximately 15 km above ground level). Both the CMAQ and CAMx air quality models can employ layer collapsing in which vertical layers in the MM5 are combined in the air quality model, which improves computational efficiency. The sensitivity of the CMAQ model estimates to the number of vertical layers was evaluated by the Western Regional Air Partnership (WRAP) and Visibility Improvements State and Tribal Association of the Southeast (VISTAS) (Tonnesen et al., 2005; 2006; Morris et al., 2004a). CMAQ model simulations were performed with no layer collapsing (i.e., the same 34 layers as used by MM5) and with various levels of layer collapsing. These studies found that using 19 vertical layers up

to 100 mb (i.e., same model top as MM5) and matching the eight lowest MM5 vertical layers near the surface produced nearly identical results as with no layer collapsing. They also found that very aggressive layer collapsing (e.g., 34 to 12 layers) produced results with substantial differences compared to no layer collapsing. Therefore, based on the WRAP/VISTAS sensitivity analysis, CENRAP adopted the 19 vertical layer configuration up to the 100 mb model top. Figure 1-3 displays the definition of the 34 MM5 vertical layers and how they were collapsed to 19 vertical layers in the air quality modeling performed by CENRAP.

MM5					CMAQ 19L				
Layer	Sigma	Pres(mb)	Height(m	Depth(m)	Layer	Sigma	Pres(mb)	Height(m)	Depth(m

Figure 1-3. MM5 34 vertical layer definitions and scheme for collapsing the 34 layers down to 19 layers for the CENRAP CMAQ and CAMx 2002 annual modeling.

1.3.6 2002 Calendar Year Selection

The calendar year 2002 was selected for CENRAP regional haze annual modeling as described in the CENRAP Modeling Protocol (Morris et al., 2004a). EPA's applicable guidance on $PM_{2.5}$/Regional Haze modeling at that time (EPA, 2001) identified specific goals to consider when selecting modeling periods for use in demonstrating reasonable progress in attaining the regional haze goals. However, since there is much in common with the goals for selecting episodes for annual and episodic $PM_{2.5}$ attainment demonstrations as well as regional haze, EPA's current guidance addresses all three in a common document. (EPA, 2007) At the time of the modeling period selection EPA had also published an updated summary of $PM_{2.5}$ and Regional Haze Modeling Guidance (Timin, 2002) that served, in some respects, as an interim placeholder until the final guidance was issued as part of the $PM_{2.5}$/regional haze NAAQS implementation process that was ultimately published in April 2007 (EPA, 2007). The interim EPA modeling guidance for episode selection (EPA, 2001; Timin, 2002) was consistent with the final EPA regional haze modeling guidance (EPA, 2007).

EPA recommends that the selection of a modeling period derive from three principal criteria:

- A variety of meteorological conditions should be covered that includes the types of meteorological conditions that produce the worst 20 percent and best 20 percent visibility days at Class I areas in the CENRAP States during the 2000-2004 baseline period;

- To the extent possible, the modeling data base should include days for which enhanced data bases (i.e. beyond routine aerometric and emissions monitoring) are available; and

- Sufficient days should be available such that relative response factors (RRFs) can be based on several (i.e., $\geq$ 15) days.

For regional haze modeling, the guidance goes further by suggesting that the preferred approach is to model a full, *representative* year (EPA, 2001, pg. 188). Moreover, the required RRF values should be based on model results averaged over the 20 percent worst and 20 percent best visibility days determined for each Class I area based on monitoring data from the 2000 – 2004 baseline period. More recent EPA guidance (Timin, 2002) suggests that states should model at least 10 worst and 10 best visibility days at each Class 1 area. EPA also lists several 'other considerations' to bear in mind when choosing potential PM/regional haze episodes including: (a) choose periods which have already been modeled, (b) choose periods which are drawn from the years upon which the current design values are based, (c) include weekend days among those chosen, and (d) choose modeling periods that meet as many episode selection criteria as possible in the maximum number of nonattainment or Class I areas as possible.

Due to limited available resources CENRAP was restricted to modeling a single calendar year. The RHR uses the five-year baseline of 2000-2004 period as the starting point for projecting future-year visibility. Thus, the modeling year should be selected from this five-year baseline period. The 2002 calendar year, which lies in the middle of the 2000-2004 Baseline, was selected for the following reasons:

- Based on available information, 2002 appears to be a fairly typical year in terms of meteorology for the 5-year Baseline period of 2000-2004;

- 2003 and 2004 appeared to be colder and wetter than typical in the eastern US;
- The enhanced IMPROVE and IMPROVE Protocol and Supersites PM monitoring data were fully operational by 2002. Much less IMPROVE monitoring data was available during 2000-2001, especially in the CENRAP region;
- IMPROVE data for 2003 and 2004 were not yet available at the time that the CENRAP modeling was initiated; and
- 2002 was being used by the other RPOs.

1.3.7 Initial Concentrations and Boundary Conditions

The CMAQ and CAMx models were operated separately for each of four quarters of the 2002 year using a ~15 day spin up period (i.e., the models were started approximately 15 days before the first day of interest in each quarter in order to limit the influence of the assumed initial concentrations, e.g., start June 15 for quarter 3 whose first day of interest is July 1). Sensitivity simulations demonstrated that with ~15 initialization days, the influence of initial concentrations (ICs) was minimal using the 36 km Inter-RPO continental U.S. modeling domain. Consequently, clean ICs were specified in the CMAQ and CAMx modeling using a ~15 day spin up period.

Boundary Conditions (BCs) (i.e., the assumed concentrations along the later edges of the 36 km modeling domain, see Figure 1-2) were based on a 2002 simulation by the GEOS-CHEM global circulation/chemistry model. GEOS-CHEM is a three-dimensional global chemistry model driven by assimilated meteorological observations from the Goddard Earth Observing System (GEOS) of the NASA Global Modeling and Assimilation Office. It is applied by research groups around the world to a wide range of atmospheric composition problems, including future climates and planetary atmospheres using general circulation model meteorology to drive the model. Central management and support of the model is provided by the Atmospheric Chemistry Modeling Group at Harvard University.

A joint RPO study was performed, coordinated by VISTAS, in which Harvard University applied the GEOS-CHEM global model for the 2002 calendar year (Jacob, Park and Logan, 2005). The University of Houston (UH) was retained to process the 2002 GEOS-CHEM output into BCs for the CMAQ model (Byun, 2004). The GEOS-CHEM simulations for the RPOs used GEOS meteorological observations for the year 2002. These were obtained from the Global Modeling and Assimilation Office(GMAO) as a 6-hourly archive (3-hour for surface quantities such as mixing depths). The data through August 2002 were from the GEOS-3 assimilation, with horizontal resolution of 1^ox1^o and 55 vertical layers. The data after August 2002 were from the updated GEOS-4 assimilation, with horizontal resolution of 1^ox1.25^o and 48 vertical layers (note 1^o latitude is equal to approximately 110 km). The GEOS-CHEM output was processed by mapping the GEOS-CHEM chemical compounds to the species in the CBM-IV chemical mechanism used by CMAQ/CAMx and mapping the GEOS-CHEM vertical layers to the 19 layer vertical layer structure used by CMAQ/CAMx in the CENRAP modeling (Byun, 2004). The results were day-specific three-hourly BC inputs for the CMAQ model. The CMAQ2CAMx processor was then used to transform the CMAQ day-specific 3-hourly BCs to the format used by CAMx.

There were several quality assurance (QA) checks of the BCs generated from the 2002 GEOS-CHEM output. The first QA/QC check was a range check to assure reasonable values. The BCs were compared against the GEOS-CHEM outputs to assure the mapping and interpolation was performed correctly. The code used to map the GEOS-CHEM output to the CMAQ BC format was obtained from UH, reviewed and the BC generation duplicated for several time periods during 2002.

1.3.8 Emissions Input Preparation

The CENRAP SMOKE emissions modeling was based on an updated 2002 emissions data for the U.S. (Pechan, 2005c,e; Reid et al., 2004a,b), 1999 emissions data for Mexico (ERG, 2006), and 2000 emissions data for Canada. These data were used to generate a final base 2002 Base G Typical (Typ02G) annual emissions database. Numerous iterations of the emissions modeling were conducted using interim databases before arriving at the final Base G emission inventories (e.g., Morris et al., 2005). The 2018 Base G base case emissions (Base18G) for most source categories in the U.S. were based on projections of the 2002 inventory assuming growth and control (Pechan, 2005d). 2018 EGU emissions were based on the run 2.1.9 of the Integrated Planning Model (IPM) updated by the CENRAP states. Canadian emissions for the Base18G scenario were based on a 2020 inventory, whereas the Mexican 1999 inventory was held constant for 2018.

The Typ02G and Base18G emission inventories represent significant improvements to the preliminary emissions modeling performed by CENRAP (Morris et al., 2005). While the preliminary 2002 modeling served its purpose to develop the infrastructure for modeling large emissions data sets and producing annual emissions simulations, much of the input data (both as inventories and ancillary data) were placeholders for actual 2002 data that were being prepared through calendar year 2005. As these actual 2002 data sets became available, they were integrated into the SMOKE modeling and QA system that was developed during the preliminary modeling, to produce a high-quality emissions data set for use in the final CMAQ and CAMx modeling. The addition of entirely new inventory categories, like marine shipping, added complexity to the modeling. By the end of the emissions data collection phase, there were 23 separate emissions processing streams covering a variety of sources categories necessary to general model-ready emission inputs for the 2002 calendar year.

Details on the emissions modeling are provided in Chapter 2 with additional information contained in Appendix B.

1.3.9 Meteorological Input Preparation

The 2002 36 km MM5 meteorological modeling was conducted by the Iowa Department of Natural Resources (IDNR) who also performed a preliminary model performance evaluation (Johnson, 2007). CENRAP performed an additional MM5 evaluation of the CENRAP 2002 36 km MM5 simulation that included a comparative evaluation against the final VISTAS 2002 36 km MM5 and an interim WRAP 2002 36 km simulation (Kemball-Cook et al., 2004). Kemball-Cook and co-workers (2004) found the following in the comparative evaluation of the CENRAP, WRAP and VISTAS 2002 36 km MM5 simulations, (details are provided in Appendix A):

Surface Meteorological Performance within the CENRAP Region

- The three MM5 simulations (CENRAP, VISTAS and WRAP) obtained comparable model performance for winds and humidity that were within model performance benchmarks.
- The WRAP MM5 simulation obtained better temperature model performance than the other two simulations due to the use of surface temperature data assimilation.
    - In the final WRAP MM5 simulation the use of surface temperature assimilation was dropped because it introduced instability in the vertical structure of the atmosphere.
- For all three runs, the Northern CENRAP domain had a cold bias in winter and a warm bias in summer.

Surface Meteorological Performance outside the CENRAP Region

- All three runs had similar surface wind model performance in the western U.S. that was outside the model performance benchmarks
- For temperature, the WRAP MM5 simulation had the best performance overall due to the surface temperature data assimilation that was dropped in the final WRAP run.
- The three runs had comparable humidity performance, although WRAP exhibited a larger wet bias in the summer and the southwestern U.S.

Upper-Air Meteorological Performance

- The VISTAS and CENRAP MM5 simulations were better able to reproduce the deep convective summer boundary layers compared to the WRAP MM5 simulations, which exhibited a smoother decrease in temperature with increase in altitude.
- CENRAP and VISTAS MM5 simulations better simulated the surface temperature inversions than WRAP.
- WRAP was better able to simulate the surface temperature.
- All three models exhibited similar vertical wind profiles.

Precipitation Performance

- In winter, all three MM5 simulations exhibited similar, fairly good, performance in reproducing the spatial distribution and magnitudes of the monthly average observed precipitation.
- In summer, all runs had a wet bias, particularly in the desert southwest where the interim WRAP run had the largest wet bias.

In conclusion, the VISTAS simulation appeared to perform best, the CENRAP MM5 model performance was generally between the VISTAS and WRAP performance, with performance more similar to VISTAS than WRAP. Although the interim WRAP MM5 simulation performed best for surface temperature due to the surface temperature data assimilation, the surface temperature assimilation degraded the MM5 upper-air performance including the ability to assimilate surface inversions and was ultimately dropped from the final WRAP MM5 simulations (Kemball-Cook et al., 2005).

The IDNR 12 km[2] MM5 simulations were also evaluated and compared with the performance of the 36 km MM5 simulation (Johnson et al., 2007). The IDNR 36 km and 12 km MM5 model performance was similar (Johnson, 2007), which supported the findings of the CMAQ and CAMx 36 and 12 km sensitivity simulations that there was little benefit of using a 12 km grid for simulating regional haze at rural Class I areas (Morris et al., 2006a). However, as noted by Tonnesen and co-workers (2005; 2006) and EPA modeling guidance (1991; 1999; 2001; 2007) this finding does not necessarily hold for 8-hour ozone and $PM_{2.5}$ modeling that is characterized by sharper concentration gradients and frequently occurs in the urban environment as compared to the more rural nature of regional haze.

1.3.10 Photolysis Rates Model Inputs

Several chemical reactions in the atmosphere are initiated by the photodissociation of various trace gases. To accurately represent the complex chemical transformations in the atmosphere, accurate estimates of these photodissociation rates must be made. The Models-3/CMAQ system includes the JPROC processor, which calculates a table of clear-sky photolysis rates (or J-values) for a specific date. JPROC uses default values for total aerosol loading and provides the option to use default ozone column data or to use measured total ozone column data. These data come from the Total Ozone Mapping Spectrometer (TOMS) satellite data. TOMS data that is available at 24-hour averages was obtained from http://toms.gsfc.nasa.gov/eptoms/ep.html. Day-specific TOMS data was used in the CMAQ radiation model (JPROC) to calculate photolysis rates. The TOMS data were missing or erroneous for several periods in 2002: August 2-12; June 10; and November 18-19. Thus, the TOMS data for August 1, 2002 was used for August 2-7 and TOMS data for August 13 was used for August 8-12. Similarly, TOMS data for June 9 was used for June 10 and data for August 17 was used for August 18-19. Note that the total column of ozone in the atmosphere is dominated by stratospheric ozone which has very little day-to-day variability so the use of TOMS data within a week or two of an actual day introduces minimal uncertainties in the modeling analysis.

JPROC produces a "look-up" table that provides photolysis rates as a function of latitude, altitude, and time (in terms of the number of hours of deviation from local noon, or hour angle). In the current CMAQ implementation, the J-values are calculated for six latitudinal bands (10º, 20º, 30º, 40º, 50º, and 60º N), seven altitudes (0 km, 1 km, 2 km, 3 km, 4 km, 5 km, and 10 km), and hourly values up to ∀8 hours of deviation from local noon. During model calculations, photolysis rates for each model grid cell are estimated by first interpolating the clear-sky photolysis rates from the look-up table using the grid cell latitude, altitude, and hour angle, followed by applying a cloud correction (attenuation) factor based on the cloud inputs from MM5.

The photolysis rates input file was prepared as separate look-up tables for each simulation day. Photolysis files are ASCII files that were visually checked for selected days to verify that photolysis are within the expected ranges.

[2] The IDNR twelve 12 km annual simulation domain was not sufficient for CENRAP's needs, thus Bret Anderson with EPA Region 7 in cooperation with Texas completed an episodic 12km simulation on a larger domain.

The Tropospheric Ultraviolet and Visible (TUV) Radiation Model (http://cprm.acd.ucar.edu/Models/TUV/) is used to generate the photolysis rates input file for CAMx. TOMS ozone data and land use data were used to develop the CAMx Albedo/Haze/Ozone input file for 2002. As for CMAQ, the missing TOMS data period in the fall of 2002 was filled-in using observed TOMS data on either side of the missing period using the same procedures as described above for CMAQ. Default land use specific albedo values were used and a constant haze value used, corresponding to rural conditions over North America.

1.3.11 Air Quality Input Preparation

Air quality data used with the CMAQ and CAMx modeling systems include: (1) Initial Concentrations (ICs) that are the assumed initial three-dimensional concentrations throughout the modeling domain.; (2) the Boundary Conditions (BCs) that are the concentrations assumed along the lateral edges of the RPO national 36 km modeling domain; and (3) air quality observations that are used in the model performance evaluation (MPE). The MPE is discussed in Section 3 and Appendix C of this TSD.

As noted in Section 1.3.7, CMAQ default clean Initial Concentrations (ICs) were used along with an approximately 15 day spin up (initialization) period to eliminate any significant influence of the ICs on the modeled concentrations for the days of interest. The same ICs were used with CAMx as well. Both CMAQ and CAMx were run for each quarter of the year. Each quarter's model run was initialized 15 days prior to the first day of interest (e.g., for quarter 3, Jul-Aug-Sep, the model was initialized on June 15, 2002 with the first modeling day of interest July 1, 2002). The CMAQ Boundary Conditions (BCs) for the Inter-RPO 36 km continental U.S. grid (Figure 1-2) were based on day-specific 3-hour averages from the output of the GEOS-CHEM global simulation model of 2002 (Jacob, Park and Logan, 2005). The 2002 GEOS-CHEM output was mapped to the species and vertical layer structure of CMAQ and interpolated to the lateral boundaries of the 36 km grid shown in Figure 1-2 (Byun, 2004).

Table 1-6 summarizes the surface air quality monitoring networks and the number of sites available in the CENRAP region that were used in the model performance evaluation. Data from these monitoring networks were also used to evaluate the CMAQ and CAMx models outside of the CENRAP region.

Table 1-6. Ground-level ambient data monitoring networks and stations available in the CENRAP states for calendar year 2002 used in the model performance evaluation.

Monitoring Network	Chemical Species Measured	Sampling Frequency; Duration	Approximate Number of Monitors
IMPROVE	Speciated $PM_{2.5}$ and PM_{10}	1 in 3 days; 24 hr	11
CASTNET	Speciated $PM_{2.5}$, Ozone	Hourly, Weekly; 1 hr, 1 Week	3
NADP	WSO4, WNO3, WNH4	Weekly	23
EPA-STN	Speciated $PM_{2.5}$	Varies; Varies	12
AIRS/AQS	CO, NO, NO_2, NO_x, O_3	Hourly; Hourly	25

1.3.12 2002 Base Case Modeling and Model Performance Evaluation

The CMAQ and CAMx models were evaluated against ambient measurements of PM species, gas-phase species and wet deposition. Table 1-6 summarizes the networks used in the model evaluation, the species measured and the averaging times and frequency of the measurements. Numerous iterations of CMAQ and CAMx 2002 base case simulations and model performance evaluations were conducted during the course of the CENRAP modeling study, most of which have been posted on the CENRAP modeling website (http://pah.cert.ucr.edu/aqm/cenrap/cmaq.shtml) and presented in previous reports and presentations for CENRAP (e.g., Morris et al., 2005; 2006a,b). Details on the final 2002 Base F 36 km CMAQ base case modeling performance evaluation are provided in Chapter 3 and Appendix C (because of the similarity between 2002 Base F and 2002 Base G and resource constraints the model evaluation was not re-conducted for Base G). In general, the model performance of the CMAQ and CAMx models for sulfate (SO4) and elemental carbon (EC) was good. Model performance for nitrate (NO3) was variable, with a summer underestimation and winter overestimation bias. Performance for organic mass carbon (OMC) was also variable, with the inclusion of the SOAmods enhancement in CMAQ Version 4.5 greatly improving the CMAQ summer OMC model performance (Morris et al., 2006c). Model performance for Soil and coarse mass (CM) was generally poor. Part of the poor performance for Soil and CM is believed to be due to measurement-model incommensurability. The IMPROVE measured values are due, in part, to local fugitive dust sources that are not captured in the model's emission inputs and the 36 km grid resolution is not conducive to modeling localized events.

1.3.13 2018 Modeling and Visibility Projections

Emissions for the 2018 base case were generated following the procedures discussed in Section 1.3.8 and Chapter 2. 2018 emissions for Electrical Generating Units (EGUs) were based on simulations of the Integrated Planning Model (IPM) that took into the account the effects of the Clean Air Interstate Rule (CAIR) on emissions from EGUs in CAIR states using an IPM realization of a CAIR cap-and-trade program. Emissions for on-road and non-road mobile sources were based on activity growth and emissions factors from the EPA MOBILE6 and NONROAD models, respectively. Area sources and non-EGU point sources were grown to 2018 levels (Pechan, 2005d). The Canadian year 2000 emissions inventory was replaced by a Canadian 2020 emissions inventory for the 2018 CMAQ/CAMx simulations. The following sources were assumed to remain constant between the 2002 and 2018 base case simulations:

- Biogenic VOC and NOx emissions from the BEIS3 biogenic emissions model;
- Wind blown dust associated with non-agricultural sources (i.e., natural wind blown fugitive dust);
- Off-shore emissions associated with off-shore marine and oil and gas production activities;
- Emissions from wildfires;
- Emissions from Mexico; and
- Global transport (i.e., emissions due to BCs from the 2002 GEOS-CHEM global chemistry model.

The results from the 2002 and 2018 CMAQ and CAMx simulations were used to project 2018 PM levels from which 2018 visibility estimates were obtained. The 2002 and 2018 modeling results were used in a relative sense to scale the observed PM concentrations from the 2000-2004 Baseline and the IMPROVE monitoring network to obtain the 2018 PM projections. The 2018/2002 modeled scaling factors are called Relative Response Factors (RRFs) and are constructed as the ratio of modeling results for the 2018 model simulation to the 2002 model simulation. Two important regional haze metrics are the average visibility for the worst 20 percent and best 20 percent days from the 2000-2004 five-year Baseline. For the 2018 visibility projections, EPA guidance recommends developing Class I area and PM species specific RRFs using the average modeling results for the worst 20 percent days during the 2002 modeling period and the 2002 and 2018 emission scenarios. The results of the CENRAP 2018 visibility projections following EPA guidance procedures (EPA, 2007a) are provided in Chapter 4 and Appendix D. CENRAP has also developed alternative procedures for visibility projections that are discussed in Chapter 5 and Appendix D. For example, much of the coarse mass (CM) impacts at Class I area IMPROVE monitors is believed to be natural and primarily from local sources that are subgrid-scale to the modeled 36 km grid so are not represented in the modeling. So, one alternative visibility projection approach is to set the RRF for CM to 1.0. That is, the CM impacts in 2018 are assumed to be the same as in the observed 2000-2004 Baseline. Similarly, the Soil impacts at IMPROVE monitors are likely mainly due to local dust sources so another alternative approach is to set the RRFs for both CM and Soil to 1.0.

The 2018 visibility projections for the worst 20 percent days are compared against a 2018 point on the Uniform Rate of Progress (URP) glidepath or the “2018 URP point”. The 2018 URP point is obtained by constructing a linear visibility glidepath in deciviews from the observed 2000-2004 Baseline (EPA, 2003a) for the worst 20 percent days to the 2064 Natural Conditions (EPA, 2003b; Pitchford, 2006). Where the linear glidepath crosses the year 2018 is the 2018 URP point. States may use the modeled 2018 visibility to help define their 2018 RPG in their RHR SIPs. The 2018 URP point is used as a benchmark to help judge the 2018 modeled visibility projections and the state’s RPG. However, as noted in EPA’s RPG guidance “The glidepath is not a presumptive target, and States may establish a RPG that provides for greater, lesser, or equivalent visibility improvement as that described by the glidepath” (EPA, 2007b). Chapter 4 and Appendix D present the 2018 visibility projections for the CENRAP Class I areas and their comparisons with the 2018 URP point using EPA default visibility projection procedures (EPA, 2007a) and EPA default URP glidepaths (EPA, 2003a,b; 2007b).

Various techniques have been developed to display the 2018 visibility modeling results including “DotPlots” that display the 2018 visibility projections as a percentage of meeting the 2018 point on the URP glidepath. A value of 100% on the DotPlot indicates that the Class I area is predicted to meet the 2018 point on the URP glidepath. Over 100% means the 2018 visibility projection obtains more visibility improvements (reductions) than required to meet the 2018 point on the URP glidepath (i.e., projected value is below the glidepath). And less than 100% indicates that fewer visibility improvements are projected than are needed to meet the 2018 point URP on the glidepath (i.e., above the glidepath). Figure 1-4 displays a DotPlot that compares the 2018 visibility projections from the CENRAP 2018 Base G CMAQ simulation with the 2018 URP point using the EPA default RRFs and alternative RRFs that set the CM and Soil RRFs to unity (i.e., assume CM and Soil are natural so remain unchanged from the 2000-2004 Baseline). For these results, the 2018 visibility projections at the Hercules Glade (HEGL1) Class I area meets the 2018 point on the URP glidepath (100%), whereas the 2018 visibility projections at Caney

Creek (CACR), Mingo (MING) and Upper Buffalo (UPBU) achieve more visibility improvements than needed to meet the 2018 URP point so are below the 2018 URP glidepath. However, the 2018 visibility projections at Breton Island comes up slightly short (~5%) of meeting the 2018 point on the URP glidepath and Wichita Mountains (WIMO) comes up approximately 40% short of meeting the 2018 point on the URP glidepath. Class I areas at the northern (e.g., VOYA, BOWA and ISLE) and southern (e.g., BIBE and GUMO) boundaries of the U.S. also fall short of achieving the 2018 URP point. High contributions of international transport and/or natural sources (e.g., wind blown dust) affect the ability of these Class I areas to be on the URP glidepath. These issues are discussed in more detail in Chapters 4 and 5.

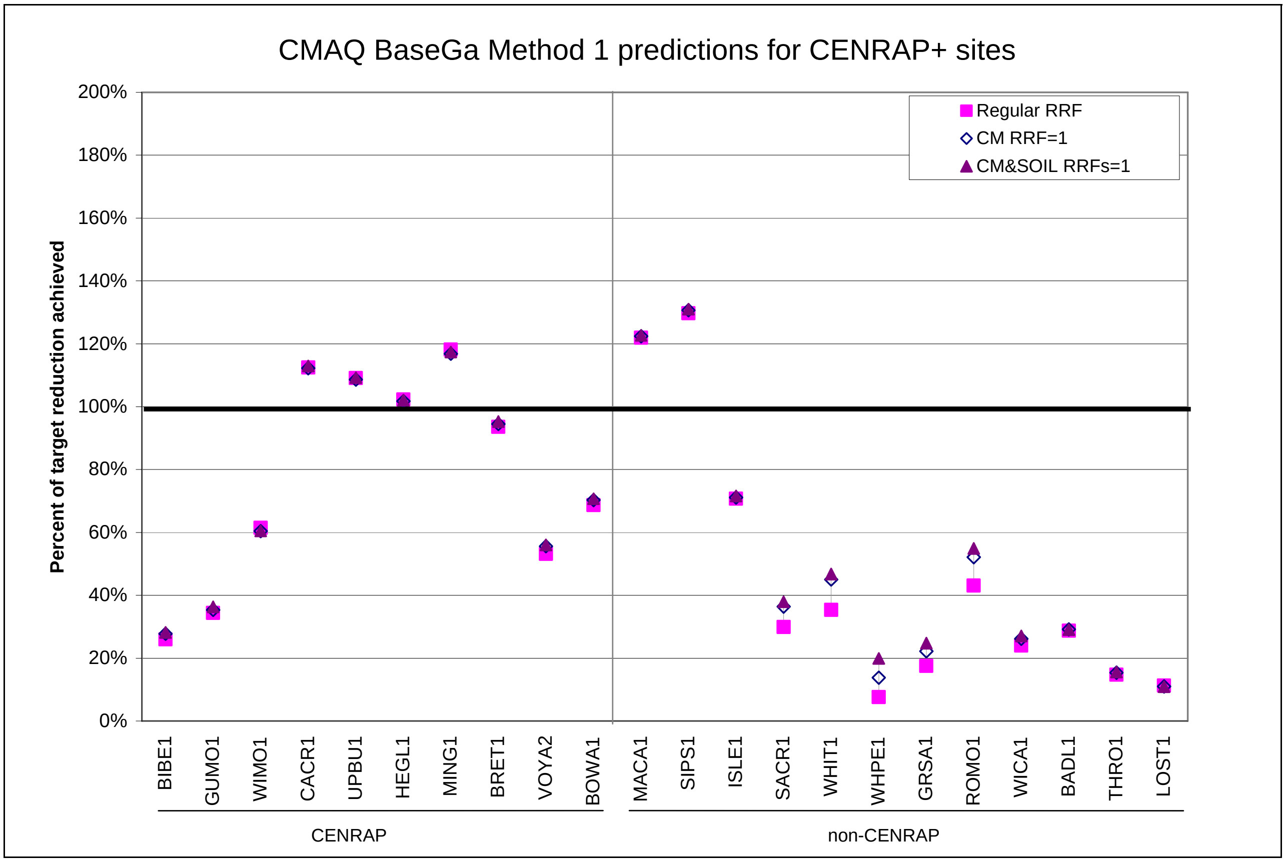

Figure 1-4. 2018 visibility projections expressed as a percent of meeting the 2018 URP point for the 2018 BaseG CMAQ base case simulation using the EPA default (EPA, 2007) Regular RRF and alternative projections procedures that set the RRFs for CM=1.0 and CM&SOIL=1.0.

1.3.14 Additional Supporting Analysis

CENRAP performed numerous supporting analyses of its modeling results including analyzing alternative glidepaths and 2018 projection Approaches and performing confirmatory analysis of the 2018 visibility projections. Details on the additional supporting analysis are contained discussed in Chapter 5, which include:

- The CENRAP 2018 visibility projections were compared with those generated by VISTAS and MRPO. There was close agreement between the CENRAP and VISTAS 2018 visibility projections at almost all common Class I areas. With the only exception being Breton Island where the CENRAP's projections were slightly more optimistic than VISTAS'. The MRPO 2018 visibility projections were less optimistic than CENRAP's at the four Arkansas-Missouri Class I area that may have been due to CENRAP's BART emission controls in CENRAP states not included in the 2018 MRPO inventory.
- Extinction based glidepaths were developed and the CENRAP 2018 visibility projections were shown to produce nearly identical estimates of achieving the 2018 URP point when using total extinction glidepaths as when the linear deciview glidepaths were used. With the extinction based glidepaths the analysis of 2018 URP could be made on a PM species-by-species basis where it was shown that 2018 extinctions due to SO4 and, to a lesser extent, NO3 and EC, achieve the URP, but the other species do not and in fact extinction due to Soil and CM is projected to get worse.
- 2018 visibility projections were made using EPA's new Modeled Attainment Test Software (MATS) program and the CENRAP Typ02G and Base18G modeling results. The CENRAP 2018 visibility projections exactly agreed with those generated by MATS with three exceptions: Breton Island, Boundary Waters and Mingo Class I areas, At these three Class I areas MATS did not produce any 2018 visibility projections due to insufficient data in the raw IMPROVE database to produce a valid observed 2000-2004 Baseline. CENRAP used filled data for these three Class I areas.
- PM Source Apportionment Technology (PSAT) modeling was conducted to estimate the contributions to visibility impairment at Class I areas by source region (e.g., states) and major source category. Source contributions were obtained for a 2002 and 2018 base case and the PSAT modeling results were implemented in a PSAT Visualization Tool that was provided to CENRAP states and others. Major findings from the PSAT source apportionment modeling include the following:
  - Sulfate from elevated point sources was the highest source category contribution to visibility impairment at CENRAP Class I areas for the worst 20 percent days.
  - International transport contributed significantly to visibility impairment at CENRAP Class I areas on the southern (BIBE and GUMO) and northern (BOWA and VOYA) borders of the U.S. and to a lesser extent at WIMO as well.
- Alternative visibility projections were made assuming that coarse mass (CM) alone and CM and Soil were natural in origin that confirmed the original 2018 visibility projections.
- Visibility projections were made using an alternative model (CAMx) that verified the projections made by CMAQ.
- The effects of International Transport were examined several ways and found that the inability of the 2018 visibility projections to achieve the 2018 URP point at the northern and southern border Class I areas was due to high contributions due to International Transport.

- Visibility trends for the worst 20 percent days, best 20 percent days and all monitored days were analyzed at CENRAP Class I areas using the period of record IMPROVE observations. At most Class I areas there was insufficient years of data to produce a discernable trend. In addition, there was significant year-to-year variability in visibility impairment with episodic events (e.g., wildfires and wind blown dust) confounding the analysis.

1.4 Organization of the Report

Chapter 1 of this TSD presents background, an overview of the approach and summary of the results of the CENRAP meteorological, emissions and air quality modeling. Appendix A contains more details on the meteorological model evaluation discussed in Chapter 1. Details on the emissions modeling are provided in Chapter 2 and Appendix B. The model performance evaluation is given in Chapter 3 and Appendix C. The 2018 visibility projections and comparisons with the 2018 URP point are provided in Chapter 4 with more details given in Appendix D. Chapter 5 contains additional supporting analysis with details on the PM source apportionment modeling and alternative projections provided in Appendices E and F, respectively. Chapter 6 lists the references cited in the report.

2.0 EMISSIONS MODELING

2.1 Emissions Modeling Overview

For the emissions modeling work conducted in support of CENRAP air quality modeling, we used updated 2002 emissions data for the U.S., 1999 emissions data for Mexico, and 2000 emissions data for Canada to generate a final base 2002 Base G Typical (Typ02G) annual emissions database. Numerous iterations of the emissions modeling were conducted using interim databases before arriving at the final Base G emission inventories. The 2002 and 2018 emissions inventories and ancillary modeling data were provided by CENRAP emissions inventory contractors (Pechan and CEP, 2005c,e; Reid et al., 2004a,b; Coe and Reid, 2003), other Regional Planning Organizations (RPOs) and EPA. Building from the CENRAP preliminary 2002 database (Pechan and CEP. 2005e) and 2018 projections (Pechan, 2005d), we integrated several updates to the inventories and ancillary data to create final emissions input files; the final simulations are referred to as 2002 Typical and 2018 Base G, or Typ02G and Base18G. We used the Sparse Matrix Operator Kernel Emissions (SMOKE) version 2.1 processing system (CEP, 2004) to prepare the inventories for input to the air quality modeling systems. The SMOKE simulations documented in this report include emissions generated for annual CMAQ and CAMx simulations at a 36-km model grid resolution, and a short-term CMAQ test simulation at a 12-km model grid resolution. We performed the modeling and quality assurance (QA) work based on the CENRAP modeling Quality Assurance Project Plan (QAPP; Morris and Tonnesen, 2004) and Modeling Protocol (Morris et al., 2004a).

The Typ02G and Base18G emission inventories represent significant improvements to the preliminary emissions modeling performed by CENRAP (Morris et al., 2005). While the preliminary 2002 modeling served its purpose to develop the infrastructure for modeling large emissions data sets and producing annual emissions simulations, much of the input data (both as inventories and ancillary data) were placeholders for actual 2002 data that were being prepared through calendar year 2005. As these actual 2002 data sets became available, they were integrated into the SMOKE modeling and QA system that was developed during the preliminary modeling, to produce a high-quality emissions data set for use in the final CMAQ and CAMx modeling. The addition of entirely new inventory categories, like marine shipping, added complexity to the modeling. By the end of the emissions data collection phase, there were 23 separate emissions processing streams covering a variety of sources categories necessary to general model-ready emission inputs for the 2002 calendar year.

2.1.1 SMOKE Emissions Modeling System Background

The purpose of SMOKE (or any emissions processor) is to process the raw emissions reported by states and EPA into gridded hourly speciated emissions required by the air quality model. Emission inventories are typically available as an annual total emissions value for each emissions source, or perhaps with an average-day emissions value. The air quality models, however, typically require emissions data on an hourly basis, for each model grid cell (and perhaps model layer), and for each model species. Consequently, emissions processing involves (at a minimum) transformation of emission inventory data by temporal allocation, chemical speciation, spatial allocation, and perhaps layer assignment, to achieve the input requirements of the air quality model. For the CENRAP modeling effort, all of these steps were needed. In

addition, CENRAP processing requires special MOBILE6 processing and growth and control of emissions for the future-year inventories. Finally, the biogenic emission processing using BEIS2 includes additional processing steps. SMOKE formulates emissions modeling in terms of sparse matrix operations. Figure 2-1 shows an example of how the matrix approach organizes the emissions processing steps for anthropogenic emissions, with the final step that creates the model-ready emissions being the merging of all the different processing streams of emissions into a total emissions input file for the air quality model. Figure 2-1 does not include all the potential processing steps, which can be different for each source category in SMOKE, but does include the major processing steps listed in the previous paragraph, except the layer assignment. Specifically, the inventory emissions are arranged as a vector of emissions, with associated vectors that include characteristics about the sources such as its state and county or source classification code (SCC). SMOKE also creates matrices that will apply the gridding, speciation, and temporal factors to the vector of emissions. In many cases, these matrices are independent from one another, and can therefore be generated in parallel. The processing approach ends with the merge step, which combines the inventory emissions vector (now an hourly inventory file) with the control, speciation, and gridding matrices to create model-ready emissions.

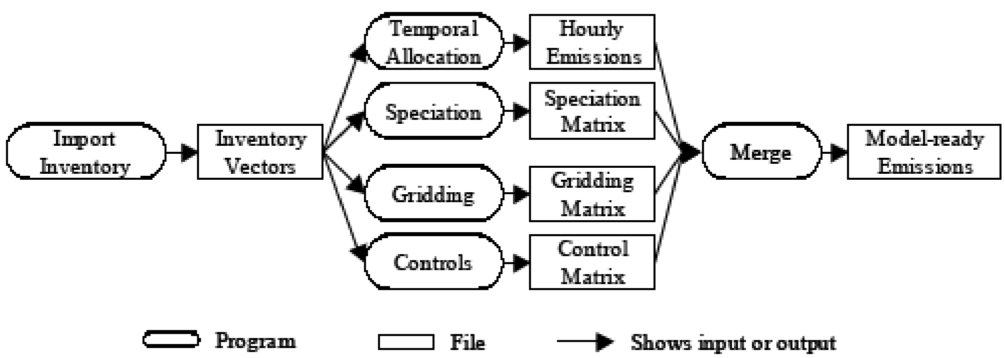

Figure 2-1. Flow diagram of major SMOKE processing steps needed by all source categories.

Temporal processing includes both seasonal or monthly adjustments and day-of-week adjustments. Emissions are known to be quite different for a typical weekday versus a typical Saturday or Sunday. For the day-of-week temporal processing step, emissions may be processed using representative Monday, weekday, Saturday, and Sunday for each month; we refer to this type of processing here as MWSS processing (note that because SMOKE operates in Greenwich Mean Time [GMT] then Monday would include some of local time Sunday so needs to be processed separately from the typical weekday). This approach significantly reduces the number of times the temporal processing step must be run. In the sections below, we have identified the cases in which we have used the MWSS processing approach. Figure 2-2 provides a schematic diagram of SMOKE/BEIS2 processing steps used in this project to generate biogenic emissions rates for Volatile Organic Compounds (VOCs) and oxides of nitrogen (NOx). Because biogenic emissions are temperature sensitive, they are generated for each day of 2002 using day-specific meteorological conditions from the MM5 meteorological model.

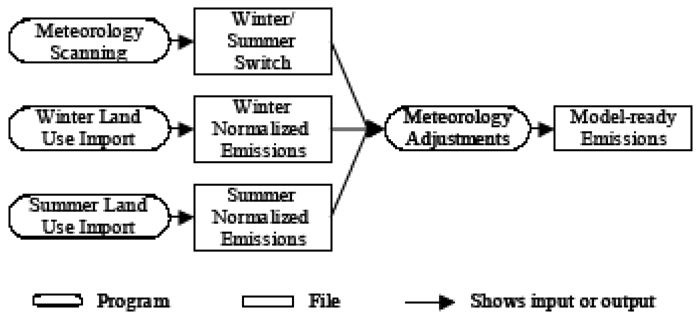

Figure 2-2. Flow diagram of SMOKE/BEIS2 processing steps.

2.1.2 SMOKE Scripts

The scripts are the interface that emissions modelers use to run SMOKE and define the set up and databases used in the emissions modeling so are important for anyone wishing to reproduce the CENRAP SMOKE emissions modeling. Many iterations of the CENRAP SMOKE emissions modeling were performed using updated and corrected emissions data and assumptions resulting in the creation of numerous SMOKE modeling scripts during the course of the study. For the CENRAP annual 2002 SMOKE emissions modeling, the default SMOKE script set up, which is based on source categories, was used to configure the scripts. We made several modifications to the default SMOKE scripts to modularize them, add error checking loops, and break up the report and logs directories by source category. The result is one script for each major source category being modeled that calls all of the SMOKE programs required for simulating that source category. 16 major source categories were modeled by SMOKE for CENRAP. An addition seven SMOKE scripts were also run to set up the emissions modeling. Table 2-1 lists all of the SMOKE scripts used for the 2002 base year modeling and the SMOKE programs called by each script. In addition to the source-specific scripts listed in Table 2-1, we also listed the SMOKE utility scripts that actually call executables, manage the log files, and manage the configuration of the SMOKE simulations.

Table 2-1. Summary of SMOKE scripts.

Source Category	Script Name	SMOKE Programs/Functions
Area	/home/aqm2/edss2/cenrap02f/subsys/smoke/ scripts/run/36km/smk_ar_base02f.csh	smkinev, grdmat, spcmat, temporal, smkmerge, smkreport
Area fire	/home/aqm2/edss2/cenrap02f/subsys/smoke/ scripts/run/36km/smk_arf_base02f.csh	smkinev, grdmat, spcmat, temporal, smkmerge, smkreport
Offshore Area	/home/aqm2/edss2/cenrap02f/subsys/smoke/ scripts/run/36km/smk_ofsar_base02f.csh	smkinev, grdmat, spcmat, temporal, smkmerge, smkreport
Non-road* Mobile	/home/aqm2/edss2/cenrap02f/subsys/smoke/ scripts/run/36km/smk_nr_base02f.csh	smkinev, grdmat, spcmat, temporal, smkmerge, smkreport
Fugitive dust	/home/aqm2/edss2/cenrap02f/subsys/smoke/ scripts/run/36km/smk_fd_base02f.csh	smkinev, grdmat, spcmat, temporal, smkmerge, smkreport
Road dust	/home/aqm2/edss2/cenrap02f/subsys/smoke/ scripts/run/36km/smk_rd_base02f.csh	smkinev, grdmat, spcmat, temporal, smkmerge, smkreport
Ammonia*	/home/aqm2/edss2/cenrap02f/subsys/smoke/ scripts/run/36km/smk_nh3_base02f.csh	smkinev, grdmat, spcmat, temporal, smkmerge, smkreport
On-road Mobile (non-VMT-based)	/home/aqm2/edss2/cenrap02f/subsys/smoke/ scripts/run/36km/smk_mb_base02f.csh	smkinev, grdmat, spcmat, temporal, smkmerge, smkreport
On-road non-US Mobile (non-VMT-based)	/home/aqm2/edss2/cenrap02f/subsys/smoke/ scripts/run/36km/smk_nusm_base02f.csh	smkinev, grdmat, spcmat, temporal, smkmerge, smkreport

WRAP Oil and Gas	/home/aqm2/edss2/cenrap02f/subsys/smoke/ scripts/run/36km/smk_wog_base02f.csh	smkinev, grdmat, spcmat, temporal, smkmerge, smkreport
Point	/home/aqm2/edss2/cenrap02f/subsys/smoke/ scripts/run/36km/smk_pt_base02f.csh	smkinev, grdmat, spcmat, laypoint, temporal, smkmerge, smkreport
Offshore point	/home/aqm2/edss2/cenrap02f/subsys/smoke/ scripts/run/36km/smk_ofs_base02f.csh	smkinev, grdmat, spcmat, laypoint, temporal, smkmerge, smkreport
Canadian Point fires	/home/aqm2/edss2/cenrap02f/subsys/smoke/ scripts/run/36km/smk_bsf_base02f.csh	smkinev, grdmat, spcmat, laypoint, temporal, smkmerge, smkreport
All point fires	/home/aqm2/edss2/cenrap02f/subsys/smoke/ scripts/run/36km/smk_alf_base02f.csh	smkinev, grdmat, spcmat, laypoint, temporal, smkmerge, smkreport
Biogenec	/home/aqm2/edss2/cenrap02f/subsys/smoke/ scripts/run/36km/smk_bg_base02f.csh	Normbies3, tmpbies3, smkmerge
n/a	/home/aqm2/edss2/cenrap02f/subsys/smoke/ scripts/run/make_invdir.csh	builds output file names and directories
n/a	/home/aqm2/edss2/cenrap02f/subsys/smoke/ scripts/run/smk_run.csh	Calls SMOKE executables for everything but projection, controls, and QA
n/a	/home/aqm2/edss2/cenrap02f/subsys/smoke/ scripts/run/qa_run.csh	Calls the SMOKE executables for running QA program & names the input/output directories for reports
n/a	/home/aqm2/edss2/cenrap02f/subsys/smoke/ scripts/run/36km/smoke_calls.csh	Calls smk_run.csh, qa_run.csh, configuration and management
n/a	/home/aqm2/edss2/cenrap02f/subsys/smoke/ Assignes/ASSIGNES.cenrap_base02f.cmaq.cb4 p25	Sets up the environment variables for use of SMOKE
n/a	/home/aqm2/edss2/cenrap02f/subsys/smoke/ Assignes/smk_mkdir	Creates the input/output directories
n/a	/home/aqm2/edss2/cenrap02f/subsys/smoke/ Assignes/setmerge_files.scr	Sets up the output environment variables for the smkmerge program

* The nr and nh3 where farther divided to nrm and nry and nh3m and nh3y for the monthly/seasonal and yearly inventories

2.1.3 SMOKE Directory Structures

The SMOKE directories can be divided into three broad categories:

1. Program Directories: These directories contain the model source code, assigns files, scripts and executables needed to run SMOKE.
2. Input Directors: These directories contain the raw emissions inventories, the meteorological data and the ancillary input files.
3. Output Directories: These directories contain all of the output from the model. Also, the output directories contain the MOBILE6 input files.

The directories are described in the Table 2-2. The final pre-merged emission file names and sources of the data re provided in Appendix B.

Table 2-2. Summary of SMOKE directories.

Category	Directory Location	Directory Contents
Program	/home/aqm2/edss2/ cenrap02f/subsys/smoke/src	SMOKE source code
	/home/aqm2/edss2/ cenrap02f/subsys/smoke/assigns	SMOKE assigns files
	/home/aqm2/edss2/ cenrap02f/subsys/smoke/scripts	SMOKE make and run scripts
	/home/aqm2/edss2/ cenrap02f/subsys/smoke/Linux2_x86pg	SMOKE executables
Input	/home/aqm2/edss2/ cenrap02f/data/met	MCIP out metrology files
	/home/aqm2/edss2/ cenrap02f/data/ge_dat	SMOKE ancillary input files
	/home/aqm2/edss2/ cenrap02f/data/inventory/cenrap2002	Raw emissions inventory files
Output	/home/aqm2/edss2/ cenrap02f/data/run_base02f/static	Non-time dependent SMOKE intermediate outputs and MOBILE6 inputs
	/home/aqm2/edss2/ cenrap02f/ data/run_base02f/scenario	Time dependent SMOKE intermediate outputs
	/home/aqm2/edss2/ cenrap02f/data/run_base02f/outputs	Model-ready SMOKE outputs
	/home/aqm2/edss2/ cenrap02f/data/reports	SMOKE QA reports

2.1.4 SMOKE Configuration

SMOKE was configured to generate emissions for all months of 2002 on the 36-km unified RPO modeling domain (Figure 1-2). For the anthropogenic emissions sources that use hourly meteorology and daily or hourly data (i.e., on-road mobile sources, point sources with CEM data, point source fires and biogenic sources) we configured SMOKE to represent the daily emissions explicitly. For the non-meteorology dependent emissions, we used a representative Saturday, Sunday, Monday, and weekday for each month as surrogate days for the entire month's emissions (we refer to this as the MWSS processing approach). For these non-meteorology dependent emissions sources we explicitly represented the holidays as Sundays. Table 2-3 lists the days that we modeled as representative days in the months that we simulated for the 2002 base year modeling. Table 2-4 lists the holidays in 2002 that were modeled as Sundays.

Table 2-3: Representative model days for 2002 base year simulation.

Saturday	Sunday	Monday	Weekday
January 5	January 6	January 7	January 4
February 2	February 3	February 4	February 5
March 2	March 3	March 4	March 5
April 6	April 7	April 8	April 2
May 4	May 5	May 6	May 7
June 8	June 9	June 3	June 4
July 6	July 7	July 8	July 3
August 3	August 4	August 5	August 6
September 7	September 8	September 9	September 10
October 5	October 6	October 7	October 8
November 2	November 3	November 4	November 5
December 7	December 8	December 9	December 10

Table 2-4: 2002 modeled holidays.

Holiday	Date
New Years	January 1, 2002 January 2, 2002
Good Friday	March 29, 2002 March 30, 2002
Memorial Day	May 27, 2002 May 28, 2002
Independence Day	July 4, 2002 July 5, 2002
Labor Day	September 2, 2002 September 3, 2002
Thanksgiving Holiday	November 28-30, 2002
Christmas Holiday	December 24-26, 2002

We used the designations in Table 2-5 to determine which months fell into each season when temporally allocating the seasonal emissions inventories. Some of the inventories for the Electrical Generating Units (EGUs) were received for Winter and Summer. Table 2-6 determines which months fell into each season

Table 2-5. Assignments of months to four seasons for use of seasonal inventory files in SMOKE.

Month	Season

May	Summer
June	Summer
July	Summer
August	Summer
September	Summer
October	Winter
November	Winter
December	Winter

2.1.5 SMOKE Processing Categories

Emissions inventories are typically divided into area, on-road mobile, non-road mobile, point, and biogenic source categories. These divisions arise from differing methods for preparing the inventories, different characteristics and attributes of the categories, and how the emissions are processed through models. Generally, emissions inventories are divided into the following source categories, which we refer to later as “SMOKE processing categories.”

- Stationary Area Sources: Sources that are treated as being spread over a spatial extent (usually a county or air district) and that are not movable (as compared to non-road mobile and on-road mobile sources). Because it is not possible to collect the emissions at each point of emission, they are estimated over larger regions. Examples of stationary

area sources are residential heating and architectural coatings. Numerous sources, such as dry cleaning facilities, may be treated either as stationary area sources or as point sources.

- On-Road Mobile Sources: Vehicular sources that travel on roadways. These sources can be computed either as being spread over a spatial extent or as being assigned to a line location (called a link). Data in on-road inventories can be either emissions or activity data. Activity data consist of vehicle miles traveled (VMT) and, optionally, vehicle speed. Activity data are used when SMOKE will be computing emission factors via another model, such as MOBILE6 (U.S. EPA, 2005). Examples of on-road mobile sources include light-duty gasoline vehicles and heavy-duty diesel vehicles.

- Non-Road Mobile Sources: These sources are engines that do not always travel on roadways. They encompass a wide variety of source types from lawn and garden equipment to locomotives and airplanes. Emission estimates for most non-road sources come from EPA's NONROAD model (OFFROAD in California). The exceptions are emissions for locomotives, airplanes, pleasure craft and commercial marine vessels.

- Point Sources: These are sources that are identified by point locations, typically because they are regulated and their locations are available in regulatory reports. In addition, elevated point sources will have their emissions allocated vertically through the model layers, as opposed to being emitted into only the first model layer. Point sources are often further subdivided into electric generating unit (EGU) sources and non-EGU sources, particularly in criteria inventories in which EGUs are a primary source of NO_x and SO_2. Examples of non-EGU point sources include chemical manufacturers and furniture refinishers. Point sources are included in both criteria and toxics inventories.

- Biogenic Land Use Data: Biogenic land use data characterize the types of vegetation that exist in either county-total or grid cell values. The biogenic land use data in North America are available using two different sets of land use categories: the Biogenic Emissions Landcover Database (BELD) version 2 (BELD2), and the BELD version 3 (BELD3) (CEP, 2004b).

In addition to these standard SMOKE processing categories, we have added other categories either to represent specific emissions processes more accurately or to integrate emissions data that are not compatible with SMOKE. Examples of emissions sectors that fall outside of the SMOKE processing categories include emissions generated from process-based models for representing windblown dust and agricultural ammonia (NH_3) sources. An emissions category with data that are not compatible with SMOKE is one with gridded emissions data sets, such as commercial marine sources. Another nonstandard emissions category that we modeled was emissions from fires. All of the emissions categories that we used to build CENRAP simulations are described in detail in the following sections.

Continuing the enhancement of the emissions source categories that we initiated during the preliminary 2002 modeling, we further refined the categories from the standard definitions listed above to include more explicit emissions sectors. The advantage of using more detailed definitions of the source categories is that it leads to more flexibility in designing control strategies, substituting new inventory or profile data into the modeling, managing the input and output data from SMOKE and conducting QA of the SMOKE outputs. The major drawback to defining more emissions source categories is the increased level of complexity and computational requirements (run times and disk space) that results from having a larger number of input data sets. Another motivation behind separating the various emissions categories is related to the size and flexibility of the input data. Some data sets, like the CENRAP on-road

mobile inventory, were so large that we had to process them separately from the rest of the sources in the on-road sector due to computational constraints. We also separated the non-road mobile and ammonia sectors into yearly and monthly inventories to facilitate the application of uniform monthly temporal profiles to the monthly data. Additional details about how we prepared the emissions inventories and ancillary data for modeling are described in Sections 2.2 through 2.16. Table 2-7 summarizes the entire group of source sectors that composed simulation Typ02G. Each emissions sector listed in the table represents an explicit SMOKE simulation. As discussed in Section 2.1.2 below, after finishing all of the source-specific simulations, we used SMOKE to combine all of the data into a single file for each day for input to the air quality modeling systems. Each subsection on the emissions sectors describes each sector in terms of the SMOKE processing category, the year covered by the inventory, and the source(s) of the data.

Additional details about the inventories are also provided, including any modifications that we made to prepare them for input into SMOKE.

Table 2-7. CENRAP Typ02G emissions categories.

Emissions Sector	Abbreviation*
Fires as Point Sources (WRAP, CENRAP, VISTAS)	Alf
Area Sources (All domain)	ar
CENRAP area fires	arf
Area fires, Anthropogenic (All domain, excluding WRAP and CENRAP)	arfa
Area fires, Wild (All domain, excluding WRAP)	arfw
Biogenic	b3
Ontario, Canada, point-source fires	bsf
Fugitive dust	fd
WRAP on-road mobile	mb
CENRAP on-road mobile	mbv_CENRAP
Other US on-road mobile	mbv
Monthly CENRAP/MRPO anthropogenic NH_3	nh3m
Ammonia from annual inventory (CENRAP)	nh3y
WRAP anthropogenic NH_3	nh3
Seasonal/Monthly non-road mobile (WRAP, CENRAP, MW)	nrm
Annual non-road mobile	nry
On-road Mobile (Non-US)	nusm
Offshore shipping (Gulf, Atlantic)	ofs
Offshore area (Gulf)	ofsar
Stationary point (All domain, including offshore)	pt
Road dust	rd
Windblown dust (All domain)	wb_dust
WRAP oil and gas	wog

*These abbreviations are used in the file naming of the SMOKE output files for each sector.

Emissions models such as SMOKE are computer programs that convert annual or daily estimates of emissions at the state or county level to hourly emissions fluxes on a uniform spatial grid that are formatted for input to an air quality model. For the Typ02G and Base18G emission inventories we prepared emissions for CMAQ version 4.5 using SMOKE version 2.1 on the UCR Linux computing cluster. SMOKE integrates annual county-level emissions inventories with source-based temporal, spatial, and chemical allocation profiles to create hourly emissions fluxes on a predefined model grid. For elevated sources that require allocation of the emissions to the vertical model layers, SMOKE integrates meteorology data to derive dynamic vertical profiles. In addition to its capacity to represent the standard emissions processing categories, SMOKE is also instrumented with the Biogenic Emissions Inventory System, version 3 (BEIS3) model for estimating biogenic emissions fluxes (U.S. EPA, 2004) and the MOBILE6 model for estimating on-road mobile emissions fluxes from county-level vehicle activity data (U.S. EPA, 2005a).

SMOKE uses C-Shell scripts as user interfaces to set configuration options and call executables. SMOKE is designed with flexible QA capabilities to generate standard and custom reports for checking the emissions modeling process. After modeling all of the source categories individually, including those categories generated outside of SMOKE, we used SMOKE to merge all of the categories together to create a single CMAQ input file per simulation day. Also, for use in the CAMx modeling, we converted the CMAQ-ready emissions estimates to CAMx-ready files using the CMAQ2CAMx converter. Additional technical details about the version of SMOKE used for final simulations are available from CEP (2004b). All scripts, data, and executables used to generate the Typ02G and Base18G emissions for CMAQ and CAMx are archived on the CENRAP computing cluster.

2.1.6 2002 and 2018 Data Sources

This section describes the procedures that the CENRAP followed to collect and prepare all emissions data for Typ02G and Base18G simulations. We discuss the sources of all inventory and ancillary data used for simulations. CENRAP worked with emissions inventory contractors, other RPOs, and EPA to collect all of the data that constitute the simulation. Table 2-8 lists all of the contacts for the various U.S. anthropogenic emission inventories we used. For the CENRAP inventories, this table lists the contacts for the contractors who prepared the inventories; for the non-CENRAP inventories it lists the contacts at the RPOs who provided us inventory data. We obtained the emissions inventories for Canada and Mexico from the U.S. EPA Emissions Factors and Inventory Group (EFIG) via the Clearinghouse for Inventories and Emissions Factors (CHIEF) website (http://www.epa.gov/ttn/chief/index.html).

As mentioned above, the refinement of these inventories involved splitting some of the inventory files into more specific source sectors. As the stationary-area-source emissions sector has traditionally been a catch-all for many types of sources, this is the inventory sector that required the greatest amount of preparation. Upon receiving all stationary-area-source inventories we extracted fugitive dust, road dust, anthropogenic NH_3, and for the non-WRAP U.S. inventories, stage II refueling sources. We retained the dust sources as separate categories that we would further refine with the application of transport factors (see Section 2.8).

We collected the ancillary data used for SMOKE modeling from several sources. SMOKE ancillary modeling data include:

- Temporal and chemical allocation factors by state, county, and source classification code (SCC);
- Spatial surrogates and cross-reference files for allocating county-level emissions to the model grid;
- Hourly gridded meteorology data;
- Stack defaults for elevated point sources;
- MOBILE6 configuration files;
- A Federal Implementation Standards (FIPS) codes (i.e., country/state/county codes) definition file;

- A Source Category Classification (SCC) codes definition file;
- A pollutant definition file; and
- Biogenic emission factors.

Except for the meteorology data and the MOBILE6 configuration files, we used default data sets provided by EPA as the basis for all of the ancillary data except for temporal profiles used for Electric Generating Units (EGUs). These profiles were developed based on CEM data from 2000 through 2003 (Pechan and CEP, 2005c). CENRAP provided the meteorology data for the simulations at 36-km and 12-km grid resolutions (Johnson, 2007). The inventory contractor who prepared the MOBILE6 inventories provided the MOBILE6 configuration files either directly or via an RPO representative; details about the sources of the MOBILE6 inputs are provided in Section 2.4. We made minor modifications to the chemical allocation, pollutant definition, and country/state/county codes files for new sources, pollutants, or counties contained in the inventories that we had not previously modeled. We made major modifications to the temporal and spatial allocation inputs, as described below.

2.1.7 Temporal Allocation

Temporally allocating annual, daily, or hourly emissions inventories in SMOKE involves combining a temporal cross-reference file and a temporal profiles file.

- Temporal cross-reference files associate monthly, weekly, and diurnal temporal profile codes with specific inventory sources, through a combination of a FIPS (country/state/county) code, an SCC, and sometimes for point sources, facility and unit identification codes.
- Temporal profiles files contain coded monthly, weekly, and diurnal profiles in terms of a percentage of emissions allocated to each temporal unit (e.g., percentage of emissions per month, weekday, or hour).

As a starting point for the temporal allocation data for simulations, we used the files generated by emission inventory contractors (Pechan and CEP, 2005c). Based on guidance from the developers of some of the inventory files, we enhanced the temporal profiles and assignments for some source categories (Pechan, 2005b).

We modified the temporal allocation data for the simulations to improve the representation of temporal emissions patterns for certain source categories. We implemented the adjusted profiles in SMOKE by modifying the temporal cross-reference file for the applicable FIPS and SCC combinations.

Updated temporal profiles for EGUs were made available for MRPO in the MRPO Base K inventory. Since the non-road emissions for IA and MN were monthly emissions developed by MRPO, new temporal profiles were created for all the SCCs in these emissions files for these two states only. The monthly profile was uniform and the weekly and diurnal profiles were kept the same as were modeled for the rest of the country.

An updated temporal profile, profile 485, based on NOAA 1971-2000 population weighted average heating degree days for home heating area source emissions was obtained from

VISTAS. This profile provided state specific updates for home heating emissions and was applied to the full inventory in place of profile 17XX.

Other additions to the Base02G temporal allocation data included updates that made by other RPOs that are applicable to their inventories. These other updates to the temporal allocation files included

- VISTAS continuous emissions monitoring (CEM)-specific profiles for EGUs in the VISTAS states;
- VISTAS agricultural burning profiles;
- Wildfire and prescribed fire profiles developed by VISTAS for the entire U.S.;
- MANE-VU on-road mobile profiles;
- WRAP weekly and diurnal road dust profiles;
- WRAP diurnal wildfire, agricultural fire, and prescribed fire profiles; and
- WRAP on-road mobile weekly and diurnal profiles.

Finally, for all of the monthly and seasonal emissions inventories, we modified the temporal cross-reference files to apply uniform monthly profiles to the sources contained in these inventories. The monthly variability is inherent in monthly and seasonal inventories and does not need to be reapplied through the temporal allocation process in SMOKE. The inventories to which we applied uniform monthly temporal profiles included:

- WRAP, CENRAP, and MRPO non-road mobile sources;
- WRAP on-road mobile sources;
- WRAP road dust; and
- CENRAP anthropogenic ammonia.

2.1.8 Spatial Allocation

SMOKE uses spatial surrogates and SCC cross-reference files to allocate county-level emissions inventories to model grid cells. Geographic information system (GIS)-calculated fractional land use values define the percentage of a grid cell that is covered by standard sets of land use categories. For example, spatial surrogates can define a grid cell as being 50% urban, 10% forest, and 40% agricultural. In addition to land use categories, spatial surrogates can also be defined by demographic or industrial units, such as population or commercial area. Similar to the temporal allocation data, an accompanying spatial cross-reference file associates the spatial surrogates (indexed with a numeric code) to SCCs. Spatial allocation with surrogates is applicable only to area and mobile sources that are provided on a county level basis. Point sources are located in the model grid cells by SMOKE based on the latitude-longitude coordinates of each source. Biogenic emissions are estimated based on 1-km^2 gridded land use information that is mapped to the model grid using a processing program such as the Multimedia Integrated Modeling System (MIMS) Spatial Allocator (CEP, 2004).

We used various sources of spatial surrogate information for the U.S., Canada, and Mexico inventories in the simulations. For the U.S. and Canadian sources, we used the EPA unified

surrogates available through the EFIG web site (EPA, 2005c). For the 36-km grid, EPA provides these data already formatted for SMOKE on the RPO Unified 36-km domain that we used for the simulations. We modified the spatial surrogates for Canada on the RPO Unified 36-km domain by adopting several surrogate categories that were enhanced by the WRAP. Table 2-9 provides details about the new Canadian spatial surrogates that were developed by the WRAP and used for CENRAP simulations. For modeling Mexico, we used Shapefiles developed for the Big Bend Regional Aerosol and Visibility Observations Study (BRAVO) modeling to create surrogates for Mexico on the RPO Unified 36-km domain (EPA, 2005c).

Table 2-9. New Canadian spatial surrogates.

Attribute	Base02a Code	Shapefile	Reference
Land area	950	can_land93_land	Natural Resources Canada (1993) AVHRR land cover data
Water area	951	can_land93_water	Natural Resources Canada (1993) AVHRR land cover data
Forest land area	952	can_land93_forest	Natural Resources Canada (1993) AVHRR land cover data
Agricultural land area	953	can_land93_agri	Natural Resources Canada (1993) AVHRR land cover data
Urban land area	954	can_land93_urban	Natural Resources Canada (1993) AVHRR land cover data
Rural land area	955	can_land93_rural	Natural Resources Canada (1993) AVHRR land cover data
Airports	956	can_airport	U.S. DOT Bureau of Transportation Statistics (2005) NORTAD 1:1,000,000 scale data
Ports	957	can_port	U.S. DOT Bureau of Transportation Statistics (2005) NORTAD 1:1,000,000 scale data
Roads	958	can_road1m	Natural Resources Canada (2001) National Scale Frameworks data
Rail	959	can_rail1m	Natural Resources Canada (1999) National Scale Frameworks data

2.2 Stationary Point Source Emissions

Stationary-point-source emissions data for SMOKE consist of (1) Inventory Data Analyzer (IDA)-formatted inventory files; (2) ancillary data for allocating the inventories in space, time, and to the Carbon Bond-IV chemistry mechanism used in CMAQ and CAMx; and (3) meteorology data for calculating plume rise from the elevated point sources. This section describes where CENRAP obtained these data, how we modeled them, and the types of QA that we performed to ensure that SMOKE processed the data as expected.

2.2.1 Data Sources

For the stationary-point-source inventories in Typ02G and Base18G, we used actual 2002 data developed by the RPOs for the U.S., version 2 of the year 2000 Canadian inventory, and the BRAVO 1999 Mexican inventory. The BRAVO inventory was updated with entirely new inventories for the six northern states of Mexico for stationary area, as well as stationary point, on-road mobile, and off-road mobile sources. Emissions for the southern states of Mexico were included for the first time in CENRAP simulations Typ02G and Base18G. These data were provided by ERG, Inc., who completed an updated 1999 emissions inventory for northern Mexico (ERG, 2006b) and delivered these data to the WRAP. The CENRAP stationary-point inventory consisted of annual county-level and tribal data provided in August of 2005 (Pechan and CEP, 2005e). The WRAP (ERG, 2006a) and VISTAS Base G (MACTEC, 2006) stationary-point inventories consisted of an annual data set and monthly CEM data for selected EGUs. The WRAP and VISTAS provided these data directly to CENRAP. We downloaded the MANE-VU stationary-point inventories from the MANE-VU web sites. MRPO base K data was downloaded and processed for SMOKE modeling by Alpine Geophysics under contract from MARAMA. UCR entered into a nondisclosure agreement with Environment Canada to obtain version 2 of the 2000 Canadian point-source inventory. This inventory represented a major improvement over the version of the data that we had used in the preliminary 2002 modeling.

Reductions anticipated from BART controls for electric generating units (EGU) in Oklahoma, Arkansas, Kansas, and Nebraska were included in projections of 2018 emissions. These anticipated reductions were based on actual operating conditions and estimated control efficiencies from utilities.

Newly permitted coal-fired utilities were included in 2018 projections. Conservatively, no IPM projected new units were removed from the simulation with the addition of the permitted facilities.

Due to missing or clearly erroneous stack parameters, several facilities in CENRAP states were relegated to default stack profiles based on SCC in the NEI QA process. Prioritizing for the largest emissions sources, these default parameters were corrected by CENRAP States and updated files were provided to modeling contractors. Final IDA input files Typ02G and Base18G for point sources reflect State corrections.

For coal-fired point and area sources, The EPA Office of Air Quality and Planning Standards (OAQPS) determined that the organic carbon fraction in the speciation profile code "NCOAL" was not representative of most coal combustion occurring in the U.S. This profile has an organic carbon fraction of 20%, which includes an adjustment factor of 1.2 to account for other atoms (like oxygen) attached to the carbon. OAQPS has reverted back to the profile code "22001" for coal combustion, which has an organic carbon fraction of 1.07% (again including the 1.2 factor adjustment). This is the same profile that EPA used for previous rulemaking efforts including the Heavy Duty Diesel Rule and Non-Road Rule, which were proposed (and publicly reviewed) prior to the introduction of the NCOAL profile.

The consensus in OAQPS is that the NCOAL profile has a high organic carbon percentage because it is based on measurements of combustion of lignite coal. With the exception of Texas, lignite is not widely used in the U.S.. Thus, OAQPS staff stopped relying on this profile as a national default profile. A new coal speciation profile developed based on Eastern bituminous

coal combustion (since much of the coal burned in the U.S. is of this type) is being developed by EPA's Office of Research and Development but was not completed for this study.

The profile recently developed for MRPO by Carnegie Mellon was provided to CENRAP and is representative of combustion of eastern bituminous coal. This profile is a more appropriate profile for most facilities in the U.S. than the default NCOAL profile.

Additionally, the "22001" profile has been flagged as problematic because of the apparent inadvertent switching of the organic carbon and elemental carbon fractions, which are 1.07% and 1.83% respectively. The report discovering the discrepancy in the profile did not offer a clear alternative to correct the problem (MACTEC, 2003).

CENRAP has continued to use the NCOAL factor for facilities burning lignite in North Dakota and Texas. For the remainder of the U.S., the MRPO profile, CMU, was used. The NCOAL factor was modified reducing the organic carbon by half and assigning the remainder to $PM_{2.5}$. The modification was at the request of Texas and was reflective of the original study for the NCOAL factor conducted in Texas (Chow, 2005). Table 2-10 summarizes the $PM_{2.5}$ speciation profiles for the NCOAL, 2201 and CMU speciation profiles for coal burning sources.

Table 2-10. PM 2.5 speciation profiles for coal-burning sources.

Profile	POC	PEC	PNO3	PSO4	PM2.5
NCOAL	0.1000	0.0100	0.0050	0.1600	0.7250
22001	0.0107	0.0183	0.0000	0.1190	0.8520
CMU	0.0263	0.0315	0.0036	0.0447	0.8938

Final simulations used improved temporal allocation and speciation information relative to the preliminary 2002 modeling; the rest of the ancillary data for modeling stationary point sources stayed the same (Mansell et al., 2005).

2.2.2 Emissions Processing

For Typ02G and Base18G simulations we configured SMOKE to process the annual inventories for the U.S., Canada, and Mexico and process hourly CEM data for the VISTAS. We configured SMOKE to allocate these emissions up to model layer 15 (approximately 2,500 m AGL), which roughly corresponds to the maximum planetary boundary layer (PBL) heights across the entire domain throughout the year. As coarse particulate matter (PMC) is not an inventory pollutant but is required by the air quality models as input species, we used SMOKE to calculate PMC during the processing as (PM_{10} - $PM_{2.5}$). With the SMOKE option WKDAY_NORMALIZE set to “No,” we treated the annual inventories based on the assumption that they represent average-day data based on a seven-day week, rather than average weekday data. We also assumed that all of the volatile organic compound (VOC) emissions in the inventories are reactive organic gas (ROG), and thus used SMOKE to convert the VOC to total organic gas (TOG) before converting the emissions into CB-IV speciation for the air quality models. To capture the differences in diurnal patterns that are contained in the CEM temporal profiles for VISTAS and CENRAP states (Base02F), we configured SMOKE to generate daily temporal matrices, as opposed to using a Monday-weekday-Saturday-Sunday (MWSS) temporal allocation approach.

To QA the stationary-point emissions, we used the procedures in the CENRAP emissions modeling QA protocol (Morris and Tonnesen, 2004) and a suite of graphical summaries. We used tabulated summaries of the input data and SMOKE script settings to document the data and configuration of SMOKE for all simulations. These QA graphics are available on the web site at: http://pah.cert.ucr.edu/aqm/cenrap/emissions.shtml

2.2.3 Uncertainties and Recommendations

There were issues with the stationary-point emissions that we left unresolved at the completion of the Typ02G and Base18G emissions modeling either because we did not feel they would have a major impact on the modeling results in CENRAP states or because we did not have alternative approaches and they represented the best available information. Canadian emissions for 2000 were found to have a significant number of missing stack parameters. These stacks when modeled with default parameters frequently resulted in lower plume heights. Stack parameters for 2000 were corrected based on cross referencing sources with the 2005 Canadian inventory for the largest emitting points. Stack parameters for many of the sources with lower emissions remain incorrect, but are assumed to have a less significant impact on CENRAP Class I areas. The 2020 projected emissions for Canada were obtained as air quality model-ready files from EPA. EPA has not confirmed that missing stack parameters were corrected for the projected inventory. It is assumed that they were not corrected and default parameters were used instead. Given confidentiality issues that surround Canadian inventories, EPA processed emissions represent the best available data.

2.3 Stationary Area Sources

Stationary-area-source emissions data for SMOKE consist of IDA-formatted inventory files and ancillary data for allocating the inventories in space, time, and to the Carbon Bond-IV chemistry mechanism used in CMAQ and CAMx. This section describes where we obtained these data, how we modeled them, and the types of QA that we performed to ensure that SMOKE processed the data as expected.

2.3.1 Data Sources

For the stationary area source inventories in the Typ02G and Base18G simulations, we used actual 2002 data developed by the RPOs for the U.S., version 2 of the year 2000 Canadian inventory, and the updated Mexican inventory, http://www.epa.gov/ttn/chief/net/mexico.html. The BRAVO inventory was updated with entirely new inventories for the six northern states of Mexico for stationary area, as well as stationary point, on-road mobile, and off-road mobile sources. Emissions for the southern states of Mexico were included for the first time in CENRAP simulations Typ02G and Base18G. The CENRAP stationary-area inventory consisted of annual county-level and tribal data provided by in August of 2005 (Pechan and CEP, 2005e). The WRAP (ERG, 2006a) and VISTAS Base G (MACTEC, 2006) stationary-area inventories consisted of an annual data set. We downloaded the MANE-VU stationary-area inventories from the MANE-VU web sites. MRPO base K data was downloaded and processed for SMOKE modeling by Alpine Geophysics under contract from MARAMA.

To prepare the stationary-area inventories for modeling, we made several modifications to the files by removing selected sources either to model them as separate source categories or to omit them from simulations completely. Using guidance provided by EPA (EPA, 2004b), we extracted fugitive and road dust sources from all stationary-area inventories for adjustment by transport factors and modeling as separate source categories (see Section 2.8). We also extracted and discarded the stage II refueling sources (Table 2-11) from the U.S. inventories; we modeled these sources with MOBILE6 as part of the on-road mobile-source emissions. We left the stage II refueling emissions in the WRAP stationary-area inventory because the on-road mobile inventory that we received for this region did not contain these emissions.

Table 2-11. Refueling SCCs removed from the non-WRAP U.S. stationary-area inventory.

SCC	Description
2501060100	Storage and Transport Petroleum and Petroleum Product Storage Gasoline Service Stations Stage 2: Total
2501060101	Storage and Transport Petroleum and Petroleum Product Storage Gasoline Service Stations Stage 2: Displacement Loss/Uncontrolled
2501060102	Storage and Transport Petroleum and Petroleum Product Storage Gasoline Service Stations Stage 2: Displacement Loss/Controlled
2501060103	Storage and Transport Petroleum and Petroleum Product Storage Gasoline Service Stations Stage 2: Spillage
2501070100	Storage and Transport Petroleum and Petroleum Product Storage Diesel Service Stations Stage 2: Total
2501070101	Storage and Transport Petroleum and Petroleum Product Storage Diesel Service Stations Stage 2: Displacement Loss/Uncontrolled
2501070102	Storage and Transport Petroleum and Petroleum Product Storage Diesel Service Stations Stage 2: Displacement Loss/Controlled
2501070103	Storage and Transport Petroleum and Petroleum Product Storage Diesel Service Stations Stage 2: Spillage

Other steps that we took to prepare the stationary-area inventories included confirming that there is no overlap between the anthropogenic NH_3 inventory (Section 2.9) and stationary area sources, and moving area-source fires in each regional inventory to separate files. In addition to these inventory modifications we made a few changes to the ancillary data files for simulation Typ02G, as described next.

Simulation Typ02G used improved temporal and spatial allocation information relative to the preliminary 2002 modeling; the rest of the ancillary data for modeling stationary area sources stayed the same as in the preliminary 2002 modeling (Mansell et al., 2005). We adopted enhanced spatial allocation data with additional area-based surrogates for Canada (Table 2-9), and added surrogates for a missing county in Colorado (Broomfield) from WRAP modeling and QA work. The WRAP had noticed when looking at the Canadian data for the preliminary 2002 modeling that forest fire emissions from the Canadian area-source inventory, which are relatively large sources of CO, NO_x, and $PM_{2.5}$, were being allocated to a surrogate for logging activities. They found similar discrepancies for other area and non-road SCCs in Canada. To improve the representation of the Canadian emissions, we adopted several land-area-based surrogates developed by the WRAP, such as forested land area, urban land area, and rural land area, and made the accompanying additions to the spatial cross-reference file to associate inventory SCCs with these surrogates. We also added spatial surrogates for Broomfield County, CO; this county was included in the inventory but was not included in the base EPA surrogates (this county was recently created from portions of other counties).

Improvements to the temporal allocation data for simulation Typ02G included the addition of several FIPS-specific profiles provided by VISTAS and CENRAP contractors (Pechan 2005b). These temporal profiles listed in Table 2-12 targeted mainly fire and agricultural NH_3 sources, such as open burning and livestock operations, respectively.

Table 2-12. New Temporal Profile Assignments for CENRAP Area Source SCCs.

2.3.2 Emissions Processing

For simulations Typ02G and Base18G we configured SMOKE to process the annual stationary-area-source inventories for the U.S., Canada, and Mexico. As PMC is not an inventory pollutant but is required by the air quality models as input species, we used SMOKE to calculate PMC during the processing as (PM_{10} - $PM_{2.5}$). With the SMOKE option WKDAY_NORMALIZE set to "Yes," we treated the annual stationary-area inventories based on the assumption that they represent average weekday data, causing SMOKE to renormalize the data to a seven-day estimate before applying any temporal adjustments. We also assumed that all of the VOC emissions in the inventories are ROG and thus used SMOKE to convert the VOC to TOG before converting the emissions into CB-IV speciation for the air quality models. We configured SMOKE to use a MWSS temporal allocation approach, as opposed to a daily temporal approach.

To QA the stationary-area emissions, we used the procedures in the CENRAP modeling QAPP and Modeling Protocol (Morris and Tonnesen, 2004; Morris et al., 2004a) and a suite of graphical summaries. We used tabulated summaries of the input data and SMOKE script settings to document the data and configuration of SMOKE for all simulations. The graphical QA summaries include, for all emissions output species, daily spatial plots summed across all model layers, daily time-series plots, and annual time-series plots. These QA graphics are available on the UCR/CENRAP web site at http://pah.cert.ucr.edu/aqm/cenrap/emissions.shtml .

2.3.3 Uncertainties and Recommendations

Most of the issues that we encountered with the stationary area sources related to the removal of certain SCCs from the base inventories for inclusion as other source categories or complete omission from simulations. We spent considerable effort on ensuring that we did not have overlap between the area inventory and the other sectors that explicitly represent sources traditionally contained in the area inventory, such as NH_3 and dust.

Both the Canadian and Mexican inventories presented minor problems that we resolved for simulation Typ02G but that can be addressed more thoroughly in future simulations. The Canadian inventory we used contained data only at the province level, essentially equivalent to a statewide rather than county-level inventory. A higher resolution inventory would have allowed us to use higher-resolution and more accurate spatial allocation data. Future modeling that uses Canadian data should move to the newly released municipality-level year 2000 inventories for Canada.

There was a discrepancy between the state and county coding in the Mexican inventory and the SMOKE file that defines acceptable FIPS codes. Differences in the ordering of the Mexican state names between these two data sets led to some of the Mexican inventory sources being mislabeled in the SMOKE QA reports. The state codes in the inventory and spatial surrogate files for two Mexican states were changed to be consistent with the SMOKE country/state/county codes file.

2.4 On-Road Mobile Sources

On-road mobile-source emissions data for SMOKE consist of IDA-formatted emissions and vehicle activity inventory files, and ancillary data for allocating the inventories in space, time, and to the Carbon Bond-IV chemistry mechanism used in CMAQ and CAMx. This section describes where we obtained these data, how we modeled them, and the types of QA that we performed to ensure that SMOKE processed the data as expected.

2.4.1 Data Sources

The SMOKE processing for CENRAP included two approaches for processing on-road mobile sources depending on the source of the data provided. The first approach was to compute mobile emissions values prior to providing them to SMOKE; we call this the pre-computed emissions approach. The second approach was to provide SMOKE with VMT data, meteorology data, and MOBILE6 inputs, and let the SMOKE/MOBILE6 module compute the mobile emissions based on these data; we call this the VMT approach. These approaches are not mutually exclusive for a single SMOKE run; therefore, we performed single SMOKE runs in which both approaches were used as follows:

- Annual VMT for computing CO, NO_x, VOC, SO2, NH3 and PM using MOBILE6 for all CENRAP States.
- Pre-computed, seasonal MOBILE6-based emissions of all pollutants for the 13 WRAP states that included pre-speciated $PM_{2.5}$ data.
- Annual VMT for computing CO, NO_x, VOC, SO2, NH3 and PM using MOBILE6 for the rest of the United States (VISTAS, MRPO and MANE-VU).
- Pre-computed, annual 1999 emissions of all pollutants for Mexico.
- Pre-computed, annual 2000 emissions of all pollutants for Canada.

For the CENRAP states, STI provided VMT data and MOBILE6 input files for all counties in the CENRAP region (Reid et al., 2004a). MOBILE6 input files were provided only for the months of January and July for 2002. MOBILE6 input files for the remaining months of 2002 had to be generated. These data were then processed within SMOKE. Using one set of MOBILE6 input files for each county in the CENRAP states resulted in compute memory requirements that were to large to process all CENRAP states together. Therefore the on-road mobile processing for the CENRAP states was split into two groups for SMOKE processing. The resulting gridded emissions data files were then merged together to obtain an on-road mobile source emissions file for the entire CENRAP region.

For the WRAP states we used actual 2002 data split into California and non-California seasonal inventories that were provided by the WRAP (Pollack et al., 2006). In addition to the standard criteria pollutants, these files contained pre-speciated $PM_{2.5}$ emissions. For the rest of the U.S. we used annual county-level activity and speed inventories with monthly, county-level MOBILE6 inputs, and hourly meteorology to estimate the hourly emissions with the SMOKE/MOBILE6 module. For the non-U.S. inventories, we used version 2 of the year 2000 Canadian inventory and the updated 1999 Mexican inventory pre-computed mobile source emissions.

2.4.2 Emissions Processing

For the Typ02G emissions modeling we configured SMOKE to process the annual on-road mobile emissions inventory data for the WRAP, Canada, and Mexico as pre-computed inventories. For the non-WRAP states, we used the SMOKE/MOBILE6 integration to process the annual activity inventories and monthly, county-based roadway information. The WRAP inventories contained pre-computed speciated PM emissions (Pollack et al, 2006) so the SMOKE PM speciation module was not used. The WRAP on-road mobile inventories were developed to represent seven-day (weekly) average emissions (as compared to the area source inventory, which represented average weekday emissions). As actual weekly average emissions, we configured SMOKE to process the WRAP on-road mobile source emissions by setting WKDAY_NORMALIZE to "No" in which case the emissions are adjusted to represent weekday and Saturday and Sunday emissions (as in contrast to the area sources where the emissions are just adjusted for Saturday and Sunday). We also assumed that all of the VOC emissions in the inventories are ROG and used SMOKE to convert the VOC to TOG before converting the emissions into CB-IV speciation for the air quality models. We configured SMOKE to create day-of-week specific rather than MWSS, temporal profiles because the WRAP on-road mobile temporal profiles contain weekly profiles that vary across the weekdays.

As noted previously, the large number of county roadway inputs for MOBILE6 processed for the non-WRAP portion of the U.S. required us to split the states mobile-source processing into three subsets because of computer memory limitations. Separate MOBILE6 input files were used for each separate county for CENRAP states, where as one MOBILE6 input file was used for several counties outside of the CENRAP region. The three subsets consisted of two sets of SMOKE/MOBILE6 simulations for the CENRAP and a simulation that computed on-road mobile emissions for the MRPO, VISTAS, and MANE-VU states. We configured MOBILE6 to use weekly temperature averaging for computing these emissions within SMOKE.

To QA the on-road mobile emissions, we used the CENRAP emissions modeling QA protocol (Morris and Tonnesen, 2004; Morris et al., 2004a) and a suite of graphical summaries. We used tabulated summaries of the input data and SMOKE script settings to document the data and configuration of SMOKE for simulations Typ02G and Base18G. The graphical QA summaries include, for all emissions output species, daily spatial plots, daily time-series plots, and annual time-series plots. These graphics are available at http://pah.cert.ucr.edu/aqm/cenrap/qa_base02b36.shtml#mb

2.4.3 Uncertainties and Recommendations

We approached the on-road mobile emissions preparation for simulation Typ02G from three different directions, which were based on the form of the input inventories and ancillary emissions data for different regions of the modeling domain:

- The WRAP region used emissions estimates pre-computed with EMFAC for California and MOBILE6 for the rest of WRAP states and processed like area sources with SMOKE adjusted from weekly to day-of-week emissions.
- The CENRAP, VISTAS, MRPO, and MANE-VU states used county-level activity data to compute emissions with the SMOKE/MOBILE6 module.

- The non-U.S. parts of the domain also had pre-computer on-road mobile source emissions so used an area-source approach for processing with SMOKE.

Different approaches for modeling a single emissions sector adds complexity and additional sources of error and inconsistencies to the modeling because of the different assumptions that went into the preparation of the input data. For example, refueling emissions from the on-road mobile sector are represented in the WRAP area-source sector but are computed with MOBILE6 for the rest of the U.S. Not using MOBILE6-based emissions for the non-U.S. portion of the domain neglects the effects of the actual 2002 meteorology on these emissions. Applying MOBILE6 outside of the U.S. is currently not possible because MOBILE6 is instrumented only for calculating emissions for the U.S. automotive fleet. The result of using MOBILE6 to calculate U.S. emissions and not using it to calculate the non-U.S. on-road mobile emissions estimates is that the non-U.S. emissions are not specific to this modeling year and the 2002 meteorological conditions, whereas the U.S. emissions are 2002-specific.

While we used the best available information to compute the on-road mobile emissions for the various portions of the modeling domain, inconsistent approaches for representing these emissions may lead to unnatural emissions gradients along political boundaries. We recommend for future work a unified approach for at least the U.S. inventories, where either we use MOBILE6 in SMOKE for the entire domain (or alternative emissions model such as CONCEPT), or we calculate the emissions with MOBILE6 outside of SMOKE and then use the resulting county-based emissions inventories.

2.5 Non-Road Mobile Sources

Non-road mobile source emissions data for SMOKE consist of annual, seasonal, and monthly IDA-formatted emission inventory files and ancillary data for allocating the inventories in space, time, and to the Carbon Bond-IV chemistry mechanism used in CMAQ and CAMx. This section describes where we obtained these data, how we modeled them, and the types of QA that we performed to ensure that SMOKE processed the data as expected.

2.5.1 Data Sources

The non-road mobile-source inventories in the Typ02G and Base18G emissions modeling used actual 2002 data developed by the RPOs for the U.S., version 2 of the year 2000 Canadian inventory and the improved 1999 Mexican inventory. The U.S. inventories consisted of annual, seasonal, and monthly inventories; the non-U.S. inventories were annual data. Pechan provided the CENRAP inventories divided between annual data for aircraft, locomotive, and commercial marine and annual files for all other non-road sources (Pechan and CEP, 2005e). Minnesota substituted the monthly MRPO Base K non-road inventory for the CENRAP inventory in their state. Iowa substituted the monthly estimates for non-road agricultural sources from the MRPO base K inventory for the CENRAP inventory. Texas provided estimates for 2002 non-road emissions in lieu of the CENRAP prepared inventory. WRAP provided non-road inventories divided between California and non-California seasonal inventories, further subdivided into aircraft, locomotives, shipping, and all other non-road mobile sources (Pollack et al., 2006). Note that the California Air Resources Board uses their own OFFROAD model for California non-

road emissions, whereas the EPA NONROAD model is used for the rest of the states (with the exception of locomotives, aircraft and shipping). With these data WRAP also provided temporal adjustments to apply to the inventories to split them between weekday and weekend emissions. We used these weekday/weekend splits to derive new weekly temporal profiles for the WRAP sources. The MRPO base K monthly non-road inventories were obtained from MRPO in NIF format and were converted to SMOKE format by Wendy Vit of the Missouri DNR. The VISTAS Base G and MANE-VU non-road mobile inventories consisted of annual county-level data (Pechan and CEP, 2005c). We received these inventories directly from the respective RPO inventory representatives. We received the Canadian 2000 inventory version 2 from the U.S. EPA EFIG (EPA, 2005d). For Mexico we used the improved 1999 inventory available at http://www.epa.gov/ttn/chief/net/mexico.html.

Along with adding the WRAP weekday/weekend emissions splits to the temporal allocation files, we also created temporal input files that apply a flat, uniform monthly profile to the monthly and seasonal non-road inventories. With the monthly and seasonal variability inherent in these inventories, we avoided applying redundant monthly profiles by splitting the inventories into seasonal/monthly and annual data. We applied the uniform monthly temporal profiles to the seasonal/monthly inventories and non-uniform monthly temporal profiles to the annual inventories. How the non-road emissions inventory data were split into those with monthly/seasonal emission and those with annual emissions is provided in Table 2-13.

Table 2-13. Non-road mobile-source inventory temporal configuration.

Region	Source	Temporal Coverage
WRAP (non-CA)	Non-road mobile	Seasonal
WRAP (CA)	Non-road mobile	Seasonal
WRAP	Aircraft	Seasonal
WRAP	Locomotive	Annual
WRAP	In-port and near-shore shipping	Annual
CENRAP	All non-road	Annual
CENRAP, IA	Non road Ag.	Monthly
VISTAS	All non-road	Annual
MRPO and MN	All non-road	Monthly
MANE-VU	All non-road	Annual
Canada	All non-road	Annual
Mexico	All non-road	Annual

Iowa elected to use the CENRAP-sponsored inventory for all of the non-road categories except for the agricultural equipment categories provided in Table 2-14. For these agricultural equipment categories, Iowa elected to use the Midwest RPO Base K inventory because this inventory provided improvements to the temporal allocation of emissions for the agricultural sector. The Base K inventory includes monthly emissions. The monthly emissions are used in the SMOKE IDA files for modeling.

Table 2-14. Non-road agricultural emissions categories where the MRPO Base K inventory was used instead of the CENRAP inventory in Iowa.

SCC	SCC Description
22600050xx	Off-highway Vehicle Gasoline, 2-Stroke: Agricultural Equipment (2 SCCs);
22650050xx	Off-highway Vehicle Gasoline, 4-Stroke: Agricultural Equipment (11 SCCs);
22670050xx	LPG : Agricultural Equipment (3 SCCs);
22680050xx	CNG : Agricultural Equipment (3 SCCs); and
22700050xx	Off-highway Vehicle Diesel : Agricultural Equipment (11 SCCs).

Texas provided annual and daily emissions for CO, CO_2, NO_x, VOC, SO_2, PM10-FIL, and PM25-FIL for several oil and gas field equipment non-road categories (Table 2-15). Texas provided authorization to change the pollutant codes from PM10-FIL to PM10-PRI and PM25-FIL to PM25-PRI.

Table 2-15. Non-road oil and gas development equipment categories that Texas provided emissions to be used instead of the CENRAP inventory.

SCC	SCC Description
2265010010	Off-highway Vehicle Gasoline, 4-Stroke : Industrial Equipment: Other Oil Field Equipment;
2268010010	CNG : Industrial Equipment : Other Oil Field Equipment; and
2270010010	Off-highway Vehicle Diesel : Industrial Equipment : Other Oil Field Equipment

Lancaster County Nebraska provided its own non-road inventory for SCC 2260000000 (Off-highway Vehicle Gasoline, 2-Stroke : 2-Stroke Gasoline except Rail and Marine: All). The CENRAP-sponsored inventories for SCCs starting with 226 in Lancaster County were removed to correct double-counting of emissions. This adjustment was made by Pechan for Base02b modeling.

2.5.2 Emissions Processing

We configured SMOKE to process all of the non-road mobile emissions inventory data as area-like inventories using spatial surrogates to grid the county-level emissions. As the WRAP inventories contained pre-computed PM emissions, we did not have to use SMOKE to compute coarse mass PM (PMC). The WRAP non-road mobile inventories represented seven-day average emissions (different from the area inventory, which represented weekday average emissions). As actual weekly average emissions, we configured SMOKE to process them by setting WKDAY_NORMALIZE to “No.” For the rest of the non-road mobile inventories we processed the data as weekday average data by setting WKDAY_NORMALIZE to “Yes.” We also assumed that all of the VOC emissions in the inventories are ROG and used SMOKE to convert the VOC to TOG before converting the emissions into CB-IV speciation for the air quality models. We configured SMOKE to create MWSS temporal intermediates rather than daily temporal files because the non-road mobile sources do not use weekly temporal profiles that vary across the weekdays, but do have very different emissions on weekdays versus weekend days.

We divided the non-road mobile emissions modeling based on whether the data were annual or seasonal/monthly inventories. This split facilitated the application of uniform monthly temporal profiles to the seasonal/monthly inventories. After processing the non-road emissions as two separate categories, non-road yearly and non-road monthly, we combined them with the rest of the emissions sectors to create model-ready emissions for CMAQ and CAMx.
To QA the non-road mobile emissions we used the procedures in the CENRAP emissions modeling QAPP (Morris and Tonnesen, 2004) and Modeling Protocol (Morris et al., 2004a) and a suite of graphical summaries. We used tabulated summaries of the input data and SMOKE script settings to document the data and configuration of SMOKE for simulations. The graphical QA summaries include, for all emissions output species, daily spatial plots, daily time-series plots, and annual time-series plots. These QA graphics are available at
http://pah.cert.ucr.edu/aqm/cenrap/qa_base02f36.shtml#nr

2.5.3 Uncertainties and Recommendations

We prepared non-road mobile emissions using a combination of inventories having different temporal resolutions and various forms of ancillary data. These different combinations of information may lead to inconsistencies in how these emissions are represented across the modeling domain. In addition, the Canadian inventories contain only province-level information and thus have low-resolution spatial and temporal profiles applied to them. The Mexican non-road emissions are deficient in the number of different SCCs contained in the inventory and the availability of spatial surrogates that are applicable to non-road mobile sources. Improvements to the temporal profiles and spatial surrogates could provide a more consistent approach to representing the non-road emissions across the entire modeling domain.

2.6 Biogenic Sources

Biogenic emissions data for SMOKE consist of input files to the BEIS3 model (EPA, 2004a). BEIS3 is a system integrated into SMOKE for deriving emissions estimates of biogenic gas-phase pollutants from land use information, emissions factors for different plant species, and hourly, gridded meteorology data. The results of BEIS3 modeling are hourly, gridded emissions fluxes formatted for input to CMAQ or CAMx. This section describes the sources of the BEIS3 input data that we used for the Typ02G and Base18G emissions, how we modeled these data and the types of QA that were performed to ensure that SMOKE processed the data as expected.

2.6.1 Data Sources

The BELD3 land use data and biogenic emissions factors that were developed during the WRAP preliminary 2002 modeling were used for the CENRAP biogenic emissions modeling (Tonnesen et al., 2005). These data included BELD3 1-km resolution land use estimates and version 0.98 of the BELD emissions factors. Since the WRAP and CENRAP use the same 36 km Inter-RPO continental U.S. modeling domain, CENRAP was able to leverage of the WRAP work performed previously.

2.6.2 Emissions Processing

We used BEIS3.12 integrated in SMOKE to prepare emissions for the simulations. Most of the preparation for the biogenic emissions processing was completed during the preliminary 2002 modeling (Morris et al., 2005). As the modeling domains did not change from the preliminary 2002 to the final modeling, we re-used the gridded land use data and vegetation emissions factors that we prepared for the preliminary simulations.

To QA the biogenic emissions, we used the CENRAP emissions modeling QAPP (Morris and Tonnesen, 2004) and Modeling Protocol (Morris et al., 2004a) and a suite of graphical summaries. We used tabulated summaries of the input data and SMOKE script settings to document the data and configuration of SMOKE for simulation Base02b. The graphical QA summaries include, for all emissions output species, daily spatial plots, daily time-series plots, and annual time-series plots. These QA graphics are available at http://pah.cert.ucr.edu/aqm/cenrap/qa_base02b36.shtml#b3

2.6.3 Uncertainties and Recommendations

The use of newer versions of BEIS (BEIS3.13) and the new MEGAN biogenic emissions models should be considered in future modeling.

2.7 Fire Emissions

Fire emissions data for SMOKE have traditionally been represented as county-level area-source inventories that were placed in only the first vertical model layer. We advanced the representation of fire emissions for air quality modeling by preparing portions of the inventory data as point sources with specific latitude-longitude coordinates for each fire centroid and pre-computed plume rise parameters that were derived from individual fire characteristics. These new inventories were based on the fire data products prepared by a CENRAP emission contractor (Reid et al., 2004b) and modified by the project team to be properly modeled as point sources. These data consist of annual, daily, and hourly IDA-formatted emissions inventory files and ancillary data for allocating the inventories in space, time, and to the Carbon Bond-IV chemistry mechanism used in CMAQ and CAMx. This section describes where we obtained these data, how we modeled them, and the types of QA performed to ensure that SMOKE processed the fire emissions data as expected.

2.7.1 Data Sources

The fire inventories in the Typ02G emissions inventory were held constant through Base18G. We used actual 2002 fire data developed by the RPOs for the U.S., version 2 of the year 2000 Canadian inventory fire data, and actual 2002 fire data for Ontario, Canada. The inventories used consisted of both area and point source data for the U.S., Canada, and Mexico. Sonoma Technology, Inc. provided the fire emissions for the CENRAP states (Reid et al., 2004b). Air Sciences provided us with the WRAP inventories divided among six different fire categories: wildfires, agricultural fires, wildland fire use, natural prescribed, anthropogenic prescribed, and non-Federal rangeland fires (Air Sciences, 2007a). These inventories consisted of annual, daily, and hourly IDA-formatted files with information on daily emissions totals and hourly plume characteristics for each fire. We received similar fire emission inventories for the other RPOS (Air Sciences, 2007b). We modeled these sources with the rest of the stationary-area-source sector.

CENRAP received data for 54 fires that occurred in Ontario during the year 2002. Information on the data code abbreviations, data definitions, and data units used in the raw data files was obtained from Mr. Rob Luik (Data Management Specialist) at the Ontario Ministry of Natural Resources (Rob.Luik@MNR. gov.on.ca). Emissions for each fire were estimated using the Emission Production Model (EPM)/CONSUME within the BlueSky framework. A fire identification code is needed to track individual fires throughout the processing. The unique fire identification code was created for each fire by concatenating the FIRE_NUMBER and CUR_DIST fields of the original data. The fire identification code also contains the FIPS code of the fire; this information is not used by BlueSky but is needed by BlueSky2Inv, the utility program that converts the BlueSky output to the SMOKE inventory format. The FIPS code 135000 was used for all fires with longitudes east of –90°, and FIPS code 135059 was used for

fires west of –90°. These FIPS codes were used to ensure that the fires would be assigned the correct time zones in later SMOKE processing. Some of the dates provided in the original data included hourly information. In all cases, the hourly information was not used leaving all data at a daily resolution.

2.7.2 Emissions Processing

SMOKE is instrumented to distribute point-source-formatted fire inventories to the vertical model layers either by using a pre-computed plume rise approach or by computing the plume rise dynamically using actual 2002 meteorology. We applied both approaches for modeling point-source fire emissions in simulation Typ02G. For the pre-computed plume rise approach, SMOKE reads an annual inventory file with information on fire locations, a daily inventory file with daily emission totals for each fire, and an hourly inventory file with hourly plume bottom, plume top, and layer 1 fractions for each fire. SMOKE uses this information to locate the fires on the horizontal model grid and to distribute the plume of each fire vertically to the model layers. Because some of these fires have plumes that reach the model top, we set the number of emissions layers for processing these inventories to the full 19 layers of the meteorology. We applied this approach to the point-source fires for the WRAP, CENRAP and VISTAS regions.
The alternative plume rise approach uses information on fuel loading and the heat flux of the fires to distribute the fires vertically to the model layers. The data are provided to SMOKE in the form of an annual inventory with information on fire locations and a daily inventory with daily emission totals for each fire, daily heat flux, and daily fuel loading. We applied this approach to the point-source fires for Ontario, Canada.

All of the point-source fires used diurnal temporal profiles and speciation profiles for VOC and $PM_{2.5}$ developed by Air Sciences (2007a) during the preliminary 2002 modeling (Morris et al., 2005).

We modeled the area-source fires for U.S. and Canada as standard stationary area sources. We applied monthly temporal profiles provided by RPOs, flat weekly temporal profiles, and the diurnal profiles developed by Air Sciences for WRAP fires (Air Sciences, 2007a), and for the rest of the RPOs we used diurnal profiles that were provided by them (Air Sciences, 2007b). We used the forestland area surrogate to distribute these emissions from the county or province level in the inventories to the model grid cells.

To QA the fire emissions, we used the procedure in the CENRAP emissions modeling QA protocol (Environ, 2004) and a suite of graphical summaries. We used tabulated summaries of the input data and SMOKE script settings to document the data and configuration of SMOKE for simulation Typ02G. The graphical QA summaries include, for all emissions output species, daily spatial plots, daily time-series plots, annual time-series plots, and vertical profiles. These QA graphics are available at: http://pah.cert.ucr.edu/aqm/cenrap/qa_typ02g36.shtml.

2.7.3 Uncertainties and Recommendations

We used forestland spatial surrogates to distribute these county level (province level for Canada) data to the model grid. Using spatial surrogates to locate fires is a crude approach that results in the artificial smearing of the emissions over too large an area. This issue can be remedied by

moving to a point-source approach for representing these fires, similar to the approach used by Air Sciences for preparing the WRAP fire inventories.

2.8 Dust Emissions

Dust emissions data for SMOKE have traditionally taken the form of county-level stationary-area-source inventories. As these emissions are correlated to meteorology, land use, and vegetative cover, we made several changes to how dust emissions are simulated by SMOKE to take these parameters into consideration. This section describes where we obtained data for windblown, fugitive, and road dust sources, how we modeled them, and the types of QA performed to ensure that SMOKE processed the data as expected.

2.8.1 Data Sources

For the fugitive dust and road dust inventories in the Typ02G emission scenario, we used actual 2002 data developed by the RPOs for the U.S., version 2 of the year 2000 Canadian inventory, and the BRAVO 1999 Mexican inventory. We extracted the fugitive dust inventories from the stationary-area inventories for each of the RPOs, Mexico, and Canada. Before modeling these data we further divided them into construction/mining sources and agricultural sources. We defined the fugitive dust sources in the Base02f modeling based on guidance provided by EPA (2004b). WRAP provide road dust emission inventories (Pollack et al., 2006). For the rest of the RPOs and Canada, we extracted the road dust SCCs from the stationary-area-source inventories. The BRAVO 1999 Mexico inventory did not contain any road dust SCCs. Table 2-16 lists the SCCs for the various fugitive and road dust sources that we modeled in the Base02f and Typ02G inventories. We applied near-source capture transport factors that are based on county-level vegetative cover to the fugitive and road dust inventories to prepare them for input to the air quality models.

For windblown dust, we used gridded emissions prepared outside of SMOKE using a land use and meteorology-based model developed under funding from the WRAP by ENVIRON and UC-Riverside (Mansell, 2005; Mansell et al., 2005).

Table 2-16. Fugitive and road dust SCCs.

Dust Category	SCCs
Fugitive dust (construction and mining)	2275085000, 2311000000, 2311010000, 2311010070, 2311020000, 2311030000, 2325000000, 2305070000, 2530000020, 2530000100, 2530000120
Fugitive dust (agricultural)	2801000003, 2801000005, 2801000008, 2805001000
Road dust	2294000000, 2296000000

2.8.2 Emissions Processing

We modeled the fugitive and road dust inventories through SMOKE using an area-source approach. We modeled these data on the assumption that they represented weekday, rather than seven-day week, emissions and thus used the SMOKE setting WKDAY_NORMALIZE to convert the data to a seven-day average. We configured SMOKE to compute PMC during the

processing as (PM_{10} - $PM_{2.5}$). Usually the records with dust do not include any other pollutants such as VOC, and NOx. For the few records that did include pollutants other than the PM we

split the records where the PMs processed with dust and the non PMs processed with the area. We configured SMOKE to create MWSS temporal intermediates rather than daily temporal files because the dust sources do not use weekly temporal profiles that vary across the weekdays.
As noted above, we used SMOKE to apply near-source transport factors to the raw fugitive and road dust inventories to prepare them for input to the air quality models. We used U.S. transport factors from work done by Pace (2005) and a 2001 land use/land cover database to develop a SMOKE input file of county and SCC-based transport factors for the U.S., Canada, and Mexico. We applied these factors to create a new set of inventories adjusted for these transport factors for all regions except VISTAS; the VISTAS dust sources that we received already had the transport factors applied to them.

We calculated the windblown dust emissions outside of SMOKE using an internally developed, process-based model. By "process-based" we refer to an emissions model that integrates information about the processes that lead to the emissions of interest, in this case windblown dust. The process-based windblown dust model developed by the WRAP considers wind speeds, precipitation history, and soil types to derive gridded dust fluxes resulting from wind disturbances for the modeling domain. More information on this model, its modes of operation, and the configuration used for simulation Base02a are available in Mansell et al. (2005).
To QA the fire emissions, we used the procedures in the CENRAP emissions modeling QAPP (Morris and Tonnesen, 2004) and Modeling Protocol (Morris et al., 2004a) and a suite of graphical summaries. We used tabulated summaries of the input data and SMOKE script settings to document the data and configuration of SMOKE for Base02f emissions. The graphical QA summaries include, for all emissions output species, daily spatial plots, daily time-series plots, and annual time-series plots. These QA graphics are available at http://pah.cert.ucr.edu/aqm/cenrap/qa_base02f36.shtml#fd for fugitive dust, http://pah.cert.ucr.edu/aqm/cenrap/qa_base02f36.shtml#rd for road dust, and http://pah.cert.ucr.edu/aqm/cenrap/qa_base02b36.shtml#wbd for windblown dust.

2.8.3 Uncertainties and Recommendations

There are several improvements that should be made to the dust emissions modeling in future simulations. We will expand the list of fugitive dust SCCs that we extract from the stationary-area-source inventories for application of transport factors. This expanded list is based on recent work by EPA (2004b). We will also explore improvements to the assumptions that we used for generating emissions with the WRAP windblown dust model. Areas of improvement in the windblown dust model include refinements to the land use data and soil characteristics, additional information about agricultural activities in the WRAP and CENRAP regions, detailed model evaluation on targeted windblown dust case studies, and the application of snow-cover and vegetative transport factors to these emissions (Mansell et al., 2005).

2.9 Ammonia Emissions

Ammonia (NH_3) emissions from agricultural activities are a major source of ammonia and are dependent on many different environmental parameters, such as meteorology, crop and soil

types, and land use. CENRAP developed NH_3 emissions for the CENRAP states (Pechan and CEP, 2005e). Ammonia emissions were estimated for 13 source categories using the Carnegie Mellon University (CMU) model and supplemental technical work; 80% of technical work was dedicated to improving emissions estimates for two source categories—livestock production and fertilizer use. For these two categories, as well as biogenic sources, improvements were made to the activity data and/or emission factors used by the CMU model. For four other source categories (industrial point sources, landfills, ammonia refrigeration, and non-road mobile sources), emissions estimates were prepared independently of the CMU model, and for the remaining six source categories (publicly owned treatment works, wildfires, domestic animals, wild animals, human respiration, and on-road mobile sources), emissions estimates were derived by running the CMU model with no alterations.

CENRAP NH_3 model emissions estimates were combined with data provided by the other RPOs to represent agricultural NH_3 emissions in simulations Typ02G and Base18G.

2.9.1 Data Sources

The WRAP provided NH_3 emissions using the WRAP NH_3 model (Mansell et al, 2005) that generated emissions for the following sectors: domestic sources, wild animals, fertilizers, soils, and livestock. MWRPO provided monthly IDA-formatted inventories reflective of base K to CENRAP that they produced from process-based models of their own, along with temporal profiles and spatial cross-reference information for these sources. Iowa elected to use the MWRPO estimates of NH_3 emissions for fertilizer application, livestock, and wastewater treatment or SCC 28017XXXXX, 28050XXXXX, and 2630020000 respectively. Minnesota reviewed the MWRPO inventory and chose to move forward with the CENRAP developed data set. The rest of the U.S., Canada, and Mexico had agricultural NH_3 emissions contained within their annual stationary-area-source inventories.

2.9.2 Emissions Processing

The WRAP NH_3 emissions were processed outside of SMOKE using the WRAP NH_3 model and provided to CENRAP as gridded, hourly emissions in network common data form (NetCDF) files. CENRAP and MWRPO provided monthly IDA-formatted, county-level NH_3 inventories that were developed separately with process-based models. We modeled these emissions like area sources with SMOKE, applying the temporal profiles and the spatial cross-referencing developed for CENRAP that we received from the MWRPO. The agricultural NH_3 emissions for the rest of the RPOs, Canada, and Mexico are contained within their stationary-area inventories. We applied the SMOKE default temporal profiles and spatial surrogates to all non-process-based NH_3 emissions.

To QA the NH_3 emissions, we used the procedures in the CENRAP modeling QAPP (Morris and Tonnesen, 2004) and Modeling Protocol (Morris et al., 2004a) and a suite of graphical summaries. We used tabulated summaries of the input data and SMOKE script settings to document the data and configuration of SMOKE for simulations Typ02G and Base18G. The graphical QA summaries include, for all emissions output species, daily spatial plots, daily time-series plots, and annual time-series plots. These QA graphics are available at http://pah.cert.ucr.edu/aqm/cenrap/index.shtml

2.9.3 Uncertainties and Recommendations

Like the other emissions categories that have traditionally been represented as stationary area sources, the agricultural NH_3 emissions sector is affected by interregional inconsistencies in the way these emissions are represented.

During the QA of the Base02a emissions, the WRAP discovered a problem with their soil NH_3 estimates. The emission factor for soil NH_3 that were used in developing these data produced too high an emission estimate from this sector. For simulations Base02B through Typ02G, we therefore removed the soil NH_3 sector completely from the WRAP domain. In future simulations we will include these emissions with a revised emission factor for NH_3 emissions from soils.

2.10 Oil and Gas Emissions

Emissions from oil and gas development activities have been poorly characterized in the past. Simulations These emissions have been sporadically reported by some states in their stationary-area-source inventories, but for the most part were missing from our preliminary modeling. In the Typ02G and Base18G simulations, significant effort was made to better represent oil and gas production emissions explicitly as both area and point sources.

2.10.1 Data Sources

Emissions from oil and gas production activities for the CENRAP states were included with the other CENRAP state emission source categories (Pechan and CEP, 2005e). We received oil and gas production emissions inventories for the WRAP states and for tribal lands in the WRAP region as stationary-area-source and stationary-point-source IDA-formatted inventories. ERG, Inc. provided the point-source inventories with the rest of the stationary-point data (ERG, 2006a). ENVIRON provided the area-source oil and gas inventories for non-CA WRAP states and for tribal lands in the WRAP region, along with spatial surrogates for allocating these data to the model grid (Russell and Pollack. 2005). Oil and gas production emissions data for outside of the WRAP region are contained in the stationary-area inventories.

2.10.2 Emissions Processing

We modeled the WRAP point-source oil and gas production emissions in combination with the rest of the stationary-point-source emissions. We modeled the WRAP area-source oil and gas production emissions explicitly as a separate category that included WRAP and tribal inventories. These data represent weekly average emissions and did not require any renormalization within SMOKE. We used spatial surrogates generated by ENVIRON to allocate these annual county-level emissions to the model grid. For all oil and gas emissions, we applied flat temporal profiles to create hourly inputs to CMAQ and CAMx.

2.10.3 Uncertainties and Recommendations

In future 2002 modeling California oil and gas production emissions should be replaced with revised data provided by the California Air Resources Board (CARB). In addition, WRAP has

updated their oil and gas production inventory for the base and future years in a Phase II work effort that substantially improved the emissions inventory estimates (Bar-Ilan et al., 2007).

2.11 MMS Off-shore Gulf of Mexico Emissions

Offshore area point source emissions include emissions in the Gulf of Mexico and off the coast of California that are associated with oil and gas drilling platforms.

2.11.1 Data Sources

We obtained year 2000 IDA-formatted point-source inventories for oil and gas platforms in the Gulf of Mexico from the Minerals Management Service (MMS) web site:
http://www.gomr.mms.gov/homepg/regulate/environ/airquality/gulfwide_emission_inventory/2000GulfwideEmissionInventory.html

We combined these with point-source data for coastal California provided to us by CARB during the preliminary 2002 modeling. We also obtained gridded area source emissions for platforms in the Gulf of Mexico from the MMS that we converted to the CENRAP 36-km model grid.

The 2000 MMS Gulf wide Emission Inventory was updated as of June 2006 to account for a change in vessel emissions in the non-point source (non-platform) database file. The point source (platform) emission inventory database file has not changed from the original version. Area source emissions from offshore activities in the Gulf of Mexico were developed from the latest estimates provided by the Minerals Management Service (MMS). The MMS inventory includes both platform and non-platform sources. The non-platform area source emissions estimates are spatially allocated to lease blocks and protraction units throughout the Gulf of Mexico. Temporal and spatial allocation cross-reference data were developed from the MMS inventory data and formatted for input to the SMOKE emissions model by Carolina Environmental Programs. These data were provided to the CENRAP emissions modeling team for implementation within SMOKE. The spatial allocation surrogates were provided for 4-km grid cells. The UCR team used these surrogates and developed surrogates for 36-km grid cells. Because these data are references to lease blocks/protraction units, rather than counties, this source category was processed separately form all other emissions using a customized reference data and SMOKE run scripts.

We modeled the offshore point and area sources as separate categories in the simulations. We used SMOKE to locate the offshore point sources on the model grid and to vertically allocate them into 15 model layers.

To QA the offshore platform emissions, we used the procedures in the CENRAP modeling QAPP (Morris and Tonnesen, 2004) and Modeling Protocol (Morris et al., 20042) and a suite of graphical summaries. We used tabulated summaries of the input data and SMOKE script settings to document the data and configuration of SMOKE for simulation Base02a. The graphical QA summaries include, for all emissions output species, daily spatial plots, daily time-series plots, and annual time-series plots. These QA graphics are available at http://pah.cert.ucr.edu/aqm/cenrap/index.shtml for the point and area sources.

2.11.2 Uncertainties and Recommendations

While the MMS data that we used were an improvement over previously modeled Gulf of Mexico platform inventories, the data were developed for a different modeling application that covered only the extreme northwestern portion of the Gulf, so they are missing large areas of the region of the Gulf that contain drilling platforms. The California offshore inventory represents an initial attempt at compiling an emission inventory for this area and contains very few sources. Future simulations will focus on improving these emissions by expanding the coverage of the offshore platform inventories for both the Gulf of Mexico and the Pacific Coast.

2.12 Off-shore Shipping Emissions

Emission inventory development for regional- and continental-scale air quality modeling has historically neglected offshore emissions sources beyond 25 miles offshore. Concern over the environmental effects of commercial shipping emissions in the Pacific on the coastal states in the WRAP region led to the development of a commercial marine shipping inventory for the Pacific. This inventory of off-shore marine vessels emissions made a substantial difference in some of the coastal western PM estimates (e.g., SO4). VISTAS developed an off-shore marine vessels inventory for the entire modeling domain that included the Pacific and Atlantic Oceans and the Gulf Of Mexico. For Typ02G and Base18G emission inventories CENRAP adopted the offshore shipping inventories developed by VISTAS.

2.12.1 Data Sources

Initially we obtained gridded annual commercial marine shipping emissions for the Pacific on the 36-km model grid from WRAP for inclusion in CENRAP simulations in the Base F modeling (Pollack et al., 2006). The commercial marine inventory contains all of the criteria pollutants contained in the non-road mobile-source inventory: CO, NO_x, VOC, NH_3, SO_2, PM_{10}, and $PM_{2.5}$. This inventory was subsequently updated in the Typ02G and Base18G modeling with the VISTAS off-shore commercial marine emissions inventory that covered the Gulf of Mexico and the Atlantic and Pacific Oceans and was based on the EPA/ARB SOx Emissions Control Area (SECA) program. Dr. James Corbett (University of Delaware) analyzed off-shore marine vessel data and worked with ENVIRON/ICF to convert to gridded emissions for the SECA grid. ENVIRON then provided SO_2, NO_X, PM and VOC emissions for the RPO 36-km grid.

2.12.2 Emissions Processing

The commercial marine shipping inventory was not processed through SMOKE. VISTAS provided the data to the as gridded text files on the 36-km model grid. These data were reformatted to the NetCDF CMAQ input format with a utility developed by UCR. The VOC inventory was converted to CB-IV speciation and the NO_x and $PM_{2.5}$ inventory pollutants to CMAQ input species with SMOKE chemical profiles for commercial shipping sources. No temporal adjustments were applied to these emissions; they use uniform monthly, daily, and diurnal profiles. An SCC for commercial marine vessels within the MMS inventory (SCC CM80002200) was accounted for in the commercial marine inventory developed for VISTAS. The duplicate emissions were removed from the MMS inventory prior to processing emissions

for Base G simulations. The duplicated emissions amounted to 19,000 TPY of NO_X and 3,184 TPY of SO_2. For simulation Typ02G and Base18G we received binary netCDF file from ENVIRON for one day and that day was used for every day of the year.
To QA the commercial marine shipping emissions, we used the procedures in the CENRAP modeling QAPP (Morris and Tonnesen, 2004) and Modeling Protocol (Morris et al., 2004a) and a suite of graphical summaries. The graphical QA summaries include, for all emissions output species, daily spatial plots, daily time-series plots, and annual time-series plots. These QA graphics are available at http://pah.cert.ucr.edu/aqm/cenrap/index.shtml.

2.12.3 Uncertainties and Recommendations

As a first attempt at representing shipping emissions in the Pacific in international waters, the WRAP and VISTAS 2002 commercial shipping inventory is a breakthrough in a historically neglected emissions category. As the RPOs evaluate the effects of these emissions on the air quality modeling, we anticipate that there will be refinements to the temporal profiles and to the vertical allocation of the emissions. Many of the stacks of large commercial ships contained in this inventory extend vertically above the first model layer. Future versions of this inventory should use higher-resolution temporal adjustments and should allocate the emissions to the appropriate model layers. Off-shore marine shipping activity is projected to increase. However, there are also the potential for emission controls on this source category (e.g., SECA program). Given these two off setting activities, the 2002 off-shore marine shipping emissions were assumed to be unchanged going from 2002 to 2018. Better estimates of 2018 marine emissions are being developed that should be considered in future modeling activities.

2.13 2018 Growth and Control

Base18G was based on grown inventories assuming on-the-books control strategies. CENRAP contracted with Pechan to deliver growth and control data for CENRAP and to consolidate growth and control information for other RPOs where available (Pechan, 2005d). The data are applicable to all source categories and pollutants included in the CENRAP 2002 emission inventory. This includes the following pollutants: sulfur oxides (SO_x), oxides of nitrogen (NO_x), volatile organic compounds (VOC), carbon monoxide (CO), ammonia (NH_3), and primary PM_{10} and $PM_{2.5}$. Some source categories were held constant between 2002 and 2018 because either stagnant growth was deemed appropriate or insufficient data was available to adequately project future growth or controls. These source categories include the following:

- Wind Blown Dust from non-agricultural land use categories.
- Emissions from wildfires.
- Emissions from Mexico.
- Global transport sources (i.e., the 2002 GEOS-CHEM boundary conditions).

2.13.1 Data Sources

CENRAP contracted with Pechan to provide growth and control factors to be applied with SMOKE for the CENRAP region (Pechan, 2005d). These growth and control parameters were based on growth estimates derived from EGAS 5.0 and control estimates assumed for

implementation of federal regulations and on-the-books state and local control programs. Emissions projections for electric generating units were developed for the RPOs with the Integrated Planning Model (IPM). The RPO 2.1.9 IPM results were subsequently modified by VISTAS, MRPO and CENRAP to reflect planned new construction and controls. The WRAP provided 2018 EGU estimates developed in coordination with State and Industry stakeholders. VISTAS, MWRPO and the WRAP provided emissions for 2018, having applied growth and control factors outside of SMOKE processing. EPA provided SMOKE processed emissions, applying both growth and controls, for Canada for the year 2020. These emissions were provided on the RPO 36-km grid. However, emissions were inexplicably processed for an alternative vertical structure. Alpine Geophysics, under contract to VISTAS reallocated the emissions through the vertical layers to more accurately reflect the vertical structure applied uniformly by the RPOs. The modified data was obtained directly from Alpine Geophysics. Emissions from Mexico were held constant between the inventory year 1999 and modeled 2002 and 2018. Improvements to the Mexican inventory have been continuously made between generation of the original BRAVO inventory and the present improved 1999 inventory. However, given the continued uncertainties in the improved inventory, no future year projections where attempted by CENRAP.

2.13.2 Emissions Processing

Growth and control factors developed by Pechan (2005d) for Arkansas did not match the final delivered inventory for Arkansas. Arkansas underwent major revisions to point and facility IDs in mid-2005. These updates were not available by the delivery date of the growth and control parameters. In coordination with Arkansas, a cross-walk was developed to correct the point and facility IDs.

The assumptions that went into the development of controls for engines covered under the RICE MACT were not consistent with the final rule. Rule penetration values for CENRAP states were adjusted to more accurately reflect the impact of the final rule.

The impact of the refinery global settlements was not incorporated into CENRAP modeling until the base G simulations. Control assumptions provided by EPA and referenced in EPA CAIR modeling were applied to the 2018 inventory. These reductions primarily impacted SO_2 emissions; however, NO_X reductions were applied in Oklahoma, Louisiana, and Minnesota.

2.13.3 Uncertainties and Recommendations

The impact of control programs is an area of uncertainty that will need continued review as the programs are implemented. Development of growth and control assumptions for Mexico will be necessary for continued refinement of the impact of international transport. CENRAP obtained estimates of increased prescribed burn activity for the Forest Service after processing of the base G simulations was underway. These estimates of increased activity should be reviewed for inclusion in future simulations. EPA developed 2020 estimates of Canadian emissions are assumed to include erroneous stack parameters previously addressed in the 2000 emissions processing. Further review of this data set is recommended.

2.14 2018 Base G C1 Control Sensitivity

CENRAP conducted a control sensitivity evaluating the impact of point source reductions given a maximum dollar per ton control level. The intent of the control sensitivity was to generate information on the impact of possible control strategies in support of the consultation process. The strategies were grouped together under a common set of criteria and not specifically identified by the states. The results of the modeling were not intended to be prescriptive; instead, they were intended to be a starting point for control discussions that would require much greater refinement.

2.14.1 Data Sources

CENRAP contracted with Alpine Geophysics to provide an evaluation of possible additional controls for the 2018 CENRAP point source inventory. These controls were in addition to on-the-books and BART controls assumed in the development of Base18F and Base18G emission scenarios. Base18F IDA files were enhanced with additional information on base level controls. The enhanced dataset was then linked with the control data contained in the 2006 release of EPA's AirControlNet software. Alpine developed cost curves for NO_X and SO_2 in 2005 dollars for the Base18F CENRAP point source inventory. Staff from Iowa DNR and Kansas DHE worked in conjunction to add area of influence data (Alpine Geophysics, 2006) and distance calculations to each Class I area in CENRAP. A variety of dollar per ton control levels were evaluated. CENRAP elected to base the sensitivity on a maximum control cost of $5,000 per ton. This selection was made with the understanding that the cost data under-represented the true cost of retrofit controls and did not take in to consideration more recent market fluctuations impacting costs of controls and construction. CENRAP refined the selection by applying controls to only those sources that met the criteria that the ratio of their emissions in tons per year to their distance to any Class I area in kilometers be less than 5. This distance weighting criteria allowed the sensitivity to focus on those sources with the greatest impact. Additional controls for other RPOs were not considered in this evaluation.

2.14.2 Emissions Processing

Sources considered for control were removed from the IDA files. Growth and control assumptions were applied outside of SMOKE and delivered to UCR as 2018 emissions. Stack parameter changes as a result of additional controls were not considered in this analysis.

2.14.3 Uncertainties and Recommendations

Given uncertainties in control costs more refined analyses should include an evaluation of retrofit control costs under present values.

2.15 Emissions Summaries

Appendix B provides details on the source of the emission files used in the CENRAP Typ02G and Base18G modeling. Also in Appendix B are sample emission summary plots, additional plots are available on the CENREAP modeling website:
http://pah.cert.ucr.edu/aqm/cenrap/emissions.shtml.

CENRAP has contracted with E.H. Pechan and Associates to provide emissions summaries used in the final Typ02G and Base18G modeling in Excel spreadsheets and in an Access database that are available on the CENRAP website (http://www.cenrap.org/projects.asp#). Figures 2-3 through 2-9 display the, respectively, SO2, NOx, VOC, PM2.5, PM10, NH3 and CO anthropogenic emissions for the CENRAP states and the Typ02G and Base18G emission scenarios. Emissions are broken down by major source sector. For the state of Texas the emissions are broken by three groups, northeast Texas, southeast Texas and remainder of Texas (west Texas).

For most states, EGUs are the largest contributor to SO2 emissions (Figure 2-3). As EGU SO2 emissions are generally projected to be reduced in the future, most states show a reduction in total SO2 emissions from 2002 to 2018. One exception to this is Louisiana for which non-EGU point source SO2 emissions are greater than for EGU and are projected to increase from 2002 to 2018. The reasons for these increases are unclear, but the growth factors for non-EGU points should be examined more carefully.

NOx emissions are fairly evenly distributed across non-EGU point, EGU point, non-road mobile, on-road mobile and area sources for the 2002 Typ02G emissions scenario (Figure 2-4). In 2018, the contributions of on-road mobile source NOx emissions is reduced dramatically, with some states also showing reductions in EGU NOx emissions as well, resulting in all states exhibiting lower NOx emissions in 2018 than 2002.

VOC emissions are dominated by area, non-road mobile, on-road mobile and non-EGU point sources in both 2002 and 2018 (Figure 2-5). VOC emissions from on-road and non-road mobile source are projected to go down in the future, whereas VOC emissions from non-EGU point and, especially, area sources are projected to increase. Thus, whether a state's total VOC emissions increase or decrease depends on the relative contributions of mobile versus area sources and the level of increase in area source VOC emissions. Note that the VOC emissions listed in Figure 2-5 do not include biogenic VOC emissions that would be greater than the anthropogenic VOC emissions shown in Figure 2-5. Note that because biogenic VOC emissions are processed using the SMOKE/BEIS module on the 36 km grid, state-wide biogenic VOC emissions summaries are not readily available.

Primary $PM_{2.5}$ emissions are primarily from road dust and fugitive dust, and for some states fires (Figure 2-6). Kansas, Oklahoma, Louisiana and Texas all have large contributions from fires not seen in the other states. Road dust and fugitive dust are the most dominate source categories for coarse particulate as well (Figure 2-7).

CENRAP developed a separate ammonia emissions for 13 categories using the CMU model including livestock and fertilizer that dominates the ammonia emissions across the CENRAP

states (Figure 2-8). Several states also have significant ammonia contributions from non-EGU point sources, whereas others do not.

CO emissions are dominated by the on-road and non-road mobile source sectors (Figure 2-9). However, states with fires also see large CO contributions from them as well. On-road mobile source CO emissions are projected to go down substantially from 2002 to 2018, whereas the other source categories are flat.

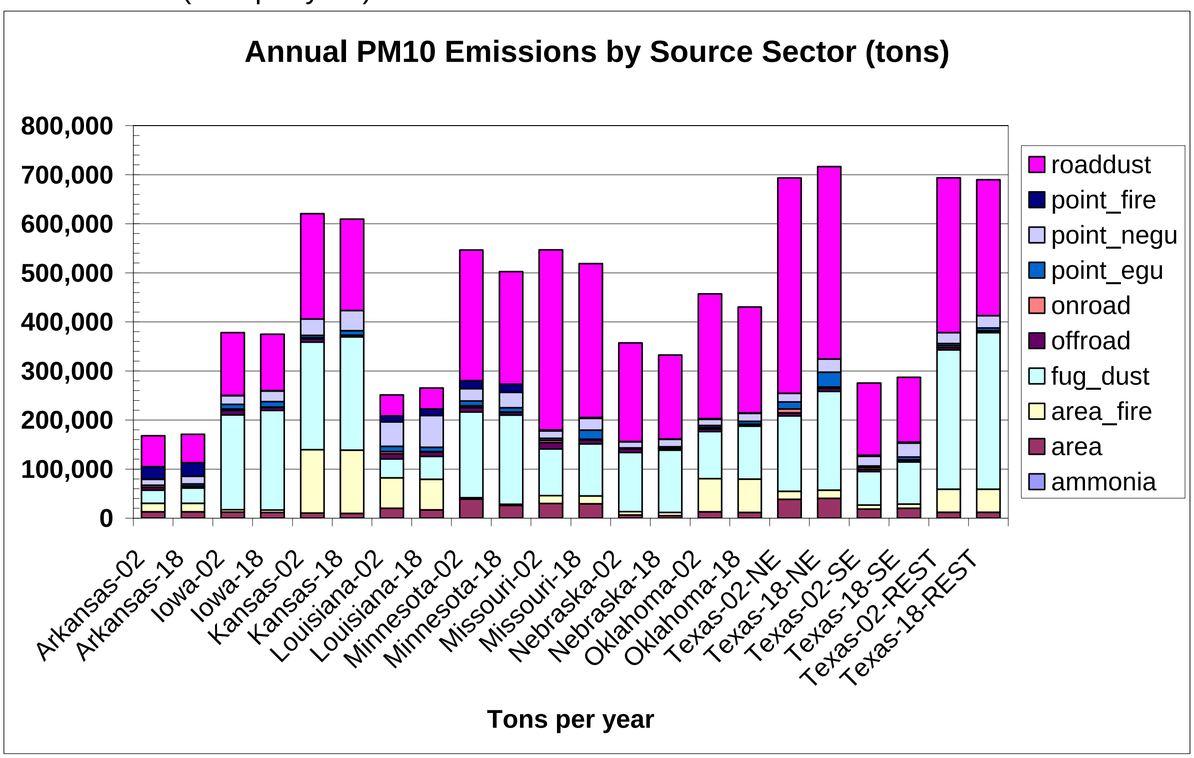

Figure 2-7. Summary of Typ02G and Base18G PM10 emissions by CENRAP state and major source sector (tons per year).

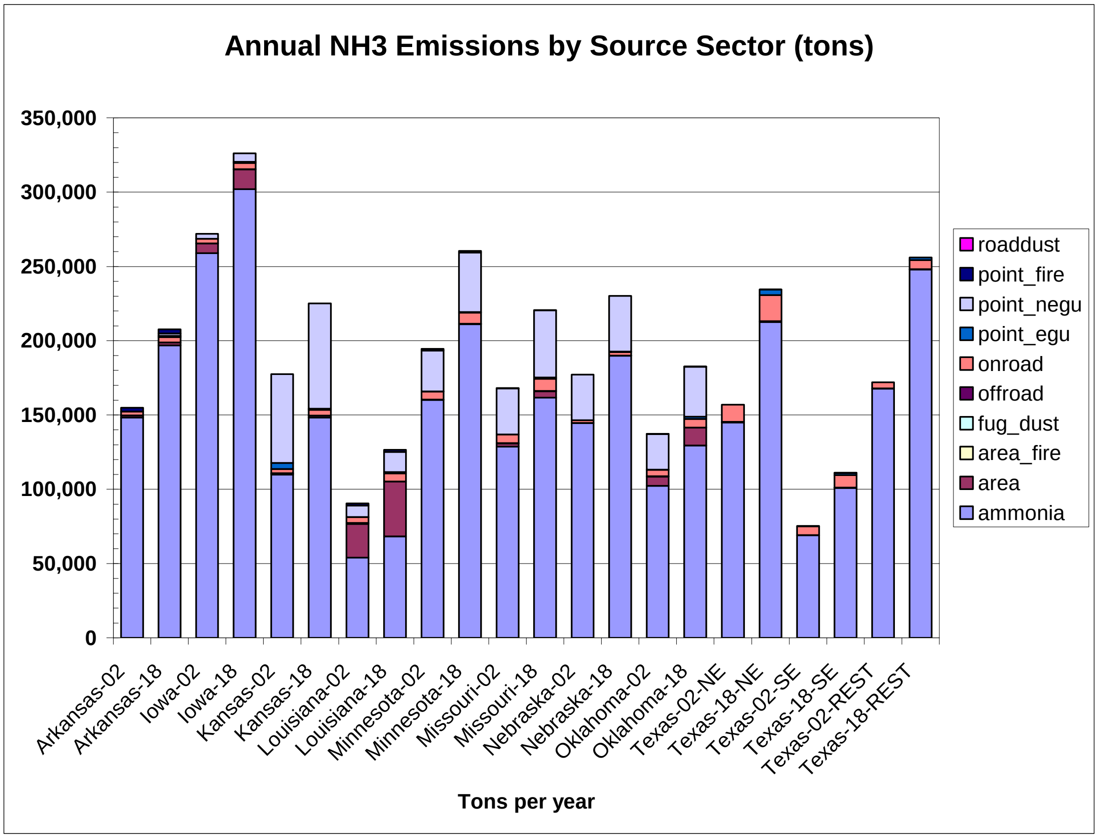

Figure 2-8. Summary of Typ02G and Base18G NH3 emissions by CENRAP state and major source sector (tons per year).

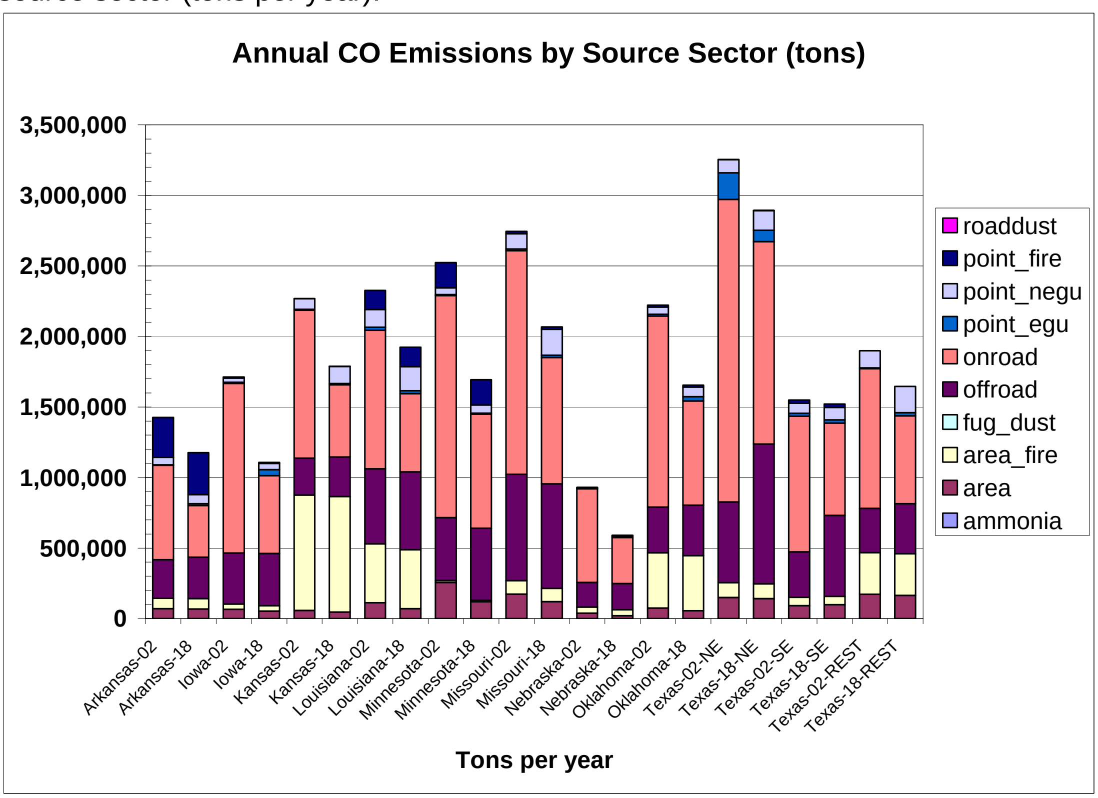

Figure 2-9. Summary of Typ02G and Base18G CO emissions by CENRAP state and major source sector (tons per year).

3.0 MODEL PERFORMANCE EVALUATION

In this Chapter we summarize the CMAQ model performance for the final 2002 36 km Base F base case simulation. Because the 2002 Base F CMAQ simulation produced nearly identical results in the U.S. as the final 2002 Base G simulation and limited resource availability, CENRAP elected not to redo the model evaluation for the 2002 Base G case. This model performance focuses on the ability of the model to predict PM species within the CENRAP region. Details on the model performance are provided in Appendix C. Previously we have documented model performance of interim versions of model base case simulations in reports (Morris et al., 2005) and presentations to the CENRAP Work Groups and POG (e.g., Morris et al., 2006a,b).

3.1 Evaluation Methodology

EPA's integrated ozone, $PM_{2.5}$ and regional haze modeling guidance calls for a comprehensive, multi-layered approach to model performance testing, consisting of the four major components: operational, diagnostic, mechanistic (or scientific) and probabilistic (EPA, 2007). The CMAQ model performance evaluation effort focused on the first two components, namely:

- **Operational Evaluation**: Tests the ability of the model to estimate PM concentrations (both fine and coarse) and the components at PM_{10} and $PM_{2.5}$ including the quantities used to characterize visibility (i.e., sulfate, nitrate, ammonium, organic carbon, elemental carbon, other $PM_{2.5}$, and coarse matter ($PM_{2.5-10}$). This evaluation examines whether the measurements are properly represented by the model predictions but does not necessarily ensure that the model is getting "the right answer for the right reason"; and

- **Diagnostic Evaluation:** Tests the ability of the model to predict visibility and extinction, PM chemical composition including PM precursors (e.g., SOx, NOx, and NH_3) and associated oxidants (e.g., ozone and nitric acid); PM size distribution; temporal variation; spatial variation; mass fluxes; and components of light extinction (i.e., scattering and absorption).

In this final model performance evaluation for the 2002 Typical Base F CMAQ simulation, the operational evaluation has been given the greatest attention since this is the primary thrust of EPA's modeling guidance. However, we have also examined certain diagnostic features dealing with the model's ability to simulate sub-regional, monthly, diurnal, gas phase and aerosol concentration distributions. In the course of the CENRAP air quality modeling and other modeling processes, numerous diagnostic sensitivity tests were performed to investigate and improve model performance. Key diagnostic tests that were performed and the results are discussed on the CENRAP modeling website: http://pah.cert.ucr.edu/aqm/cenrap/index.shtml.

3.2 Ambient Air Quality Data used in the Evaluation

The ground-level model evaluation database for 2002 was compiled by the modeling team using several routine and research-grade databases. The first is the routine gas-phase concentration measurements for ozone, SO_2, NO_2 and CO archived in EPA's Aerometric Information Retrieval System (AIRS) Air Quality System (AQS) database. Other sources of observed information come from the various PM monitoring networks in the U.S. These include the Interagency Monitoring of Protected Visual Environments (IMPROVE); Clean Air Status and Trends Network (CASTNET); EPA Speciation Trends Network (STN) of $PM_{2.5}$ species; and National Acid Deposition Program (NADP). During the course of the CENRAP modeling, the numerous base case simulations were evaluated across the continental U.S. (e.g., Morris et al., 2005). In this section and in Appendix C we focus our evaluation on model performance within the CENRAP region.

3.2 Operational Model Evaluation Approach

The CENRAP modeling databases will be used to develop the visibility State Implementation Plan (SIP) as required by the Regional Haze Rule (RHR). Accordingly, the primary focus of the operational evaluation in this report is on the six components of fine particulate ($PM_{2.5}$) and coarse mass ($PM_{2.5-10}$) within the CENRAP region that are used to characterize visibility at Class I areas:

- Sulfate (SO4);
- Particulate Nitrate (NO3);
- Elemental Carbon (EC);
- Organic Mass Carbon (OMC);
- Other inorganic fine particulate (IP or Soil); and
- Coarse Mass (CM).

The model performance for ozone, precursors, and product species (e.g., SO_4 , NO_3, NH_4 and HNO_3) is also evaluated to build confidence that the modeling system is sufficiently reliable to project future-year visibility.

3.3 Model Performance Goals and Criteria

The issue of model performance goals for PM species is an area of ongoing research and debate. For ozone modeling, EPA has established performance goals for 1-hour ozone: normalized mean bias and gross error of #±15% and #35%, respectively (EPA, 1991). EPA's draft fine particulate modeling guidance notes that performance goals for ozone should be viewed as upper bounds of model performance that PM models may not be able to always achieve and that we should demand better model performance for PM components that make up a larger fraction of the PM mass than those that are minor contributors (EPA, 2001). EPA's final modeling guidance does not list any specific model performance goals for PM and visibility modeling and instead provides a summary of PM model performance across several historical applications that can be used for comparisons, if desired. Measuring PM species is not as precise as ozone monitoring. In fact, the uncertainty in measurement techniques for some PM species is likely to

exceed the more stringent model performance goals, such as those for ozone. For example, recent comparisons of the PM species measurements using the IMPROVE and STN measurement technologies found uncertainties of approximately ∀20% (SO4) to ∀50% (EC) (Solomon et al., 2004).

For the CENRAP modeling we have adopted three levels of model performance goals and criteria for bias and gross error as listed in Table 3-1. Note that we are not suggesting that these performance goals be adopted as guidance. Rather, we are just using them to frame and put the PM model performance into context and to facilitate model performance intercomparison across episodes, species, models and sensitivity tests.

Table 3-1. Model performance goals and criteria used to assist in interpreting modeling results.

Fractional Bias	Fractional Gross Error	Comment
#∀15%	#35%	Ozone model performance goal for which PM model performance would be considered "good" – note that for many PM species measurement uncertainties may exceed this goal.
#∀30%	#50%	Proposed PM model performance goal that we would hope each PM species could meet
#∀60%	#75%	Proposed PM criteria above which indicates potential fundamental problems with the modeling system.

As noted in EPA's PM modeling guidance, less abundant PM species should have less stringent performance goals (EPA, 2001; 2007). Accordingly, we are also using performance goals that are a continuous function of average concentrations, as proposed by Dr. James Boylan at the Georgia Department of Natural Resources (GA DNR), that have the following features (Boylan, 2004):

- Asymptotically approaching proposed performance goals or criteria (i.e., the ∀30%/50% and ∀60%/75% bias/error levels listed in Table 3-1) when the mean of the observed concentrations are greater than 2.5 ug/m^3.
- Approaching 200% error and ∀200% bias when the mean of the observed concentrations are extremely small.

Bias and error are plotted as a function of average concentrations. As the mean concentration approaches zero, the bias performance goal and criteria flare out to ∀200% creating a horn shape, hence the name "Bugle Plots". Dr. Boylan has defined three Zones of model performance: Zone 1 meets the ∀30%/50% bias/error performance goal and is considered "good" model performance; Zone 2 lies between the ∀30%/50% performance goal and ∀60%/75% performance criteria and is an area where concern for model performance is raised; and Zone 3 lies above the ∀60%/75% performance criteria and is an area of questionable model performance.

3.4 Key Measures of Model Performance

Although we have generated numerous statistical performance measures (see Table C-2 in Appendix C) that are available on the CENRAP modeling website, when comparing model performance across months, subdomains, networks, grid resolution, models, studies, etc. it is useful to have a few key measurement statistics to be used to facilitate the comparisons. It is also useful to have a subset of months within the 2002 year that can represent the entire year so that a more focused evaluation can be conducted. We have found that the Mean Fractional Bias and Mean Fractional Gross Error appear to be the most consistent descriptive measure of model performance (Morris et al., 2004b; 2005). The Fractional Bias and Error are normalized by the average of the observed and predicted value (see Table C-2) because it provides descriptive power across different magnitudes of the model and observed concentrations and is bounded by -200% to +200%. This is in contrast to the normalized bias and error (as recommended for ozone performance goals, EPA, 1991) that is normalized by just the observed value so can "blow up" to infinity as the observed value approaches zero. In Appendix C we perform a focused evaluation of model performance for PM and gaseous species and four months of the 2002 year that are used to represent the seasonal variation in performance:

- January
- April
- July
- October

Scatter plots of model predictions and observations for each PM species are presented for each of the four months along with performance statistics and predicted and observed time series plots at each CENRAP Class I area. Summary plots of monthly fractional bias and error are also presented.

3.5 Operational Model Performance Evaluation

A summary of the operational evaluation is presented below. Just the monthly fractional bias performance metrics for each PM species using bar charts and Bugle Plots are presented in this section. The reader is referred to Appendix C for the complete model performance evaluation.

3.5.1 Sulfate (SO4) Model Performance

Figure 3-1 compares the monthly SO4 fractional bias across the CENRAP region for the IMPROVE, STN and CASTNet monitoring networks. An underprediction bias is clearly evident the first 8-10 months of the year. This underestimation bias is greatest across the CASTNet network which persists throughout the year. The SO4 underprediction is not as severe for the STN network and it is minimal by August becoming a slight overprediction in September. For the IMPROVE network, the SO4 fractional bias is < ±20% for the first 2 and last 3 months of the year and ranges from -30% to -50% for the late Spring and Summer months.

Figure 3-1 also includes a Bugle Plot of monthly SO4 fractional bias statistics (for Bugle Plot of fractional gross error see Appendix C) and compares them against the proposed PM model

performance goal and criteria (see Table 3-1). For the STN network, SO4 model performance meets the proposed performance goal for all months. For the IMPROVE network, approximately half of the months achieve the proposed PM performance goal with the other half outside of the goal, but within the performance criteria. Across the CASTNet network, most months are outside of the proposed goal but are within the criteria. The CASTNet fractional bias for some months is right at the performance criteria (≤±60%). With the exception of two IMPROVE months, the monthly SO4 fractional bias performance statistics achieve the proposed PM model performance goal.

3.5.2 Nitrate (NO3) Model Performance

Monthly NO3 model performance across the CENRAP region is characterized by a summer underestimation and winter overestimation bias (Figure 3-2). The summer underestimation bias is more severe, exceeding -100%. Whereas, the winter overestimation bias is approximately 50%. So based on statistics alone, it appears the summer underestimation bias is a bigger concern than the winter overestimation bias. However, the Bugle Plots in the bottom part of Figure 3-2 show that the summer underestimation bias occurs when NO3 is very low and is not an important component of PM and visibility impairment. These summer values occur in the flared horn part of the Bugle Plot and the summer NO3 performance, in most cases, achieves the model performance goal and always achieves the performance criteria. Whereas, the winter overstated NO3 performance for the most part doesn’t meet the performance goal and there are some months/networks that also don’t meet the performance criteria.

3.5.3 Organic Matter Carbon (OMC) Model Performance

The OMC monthly fractional bias across IMPROVE and STN sites in the CENRAP region are shown in Figure 3-3. The fractional bias for OMC at the IMPROVE sites is quite good throughout the year with values generally within ±20%, albeit with a slight winter overestimation and summer underestimation bias. At the urban STN sites, the model exhibits an underestimation bias throughout the year that ranges from -20% to -50%. The urban underestimation of OMC is a fairly common occurrence and suggests there may be missing sources of organic aerosol emissions in the modeling inventory.

The good performance of the model for OMC at the IMPROVE sites is also reflected in the Bugle Plot (Figure 3-3, bottom) with the bias achieving the proposed PM model performance goal for all months of the year. At the STN sites, however, the OMC bias falls between the proposed PM model performance goal and criteria, with error right at the goal for most months.

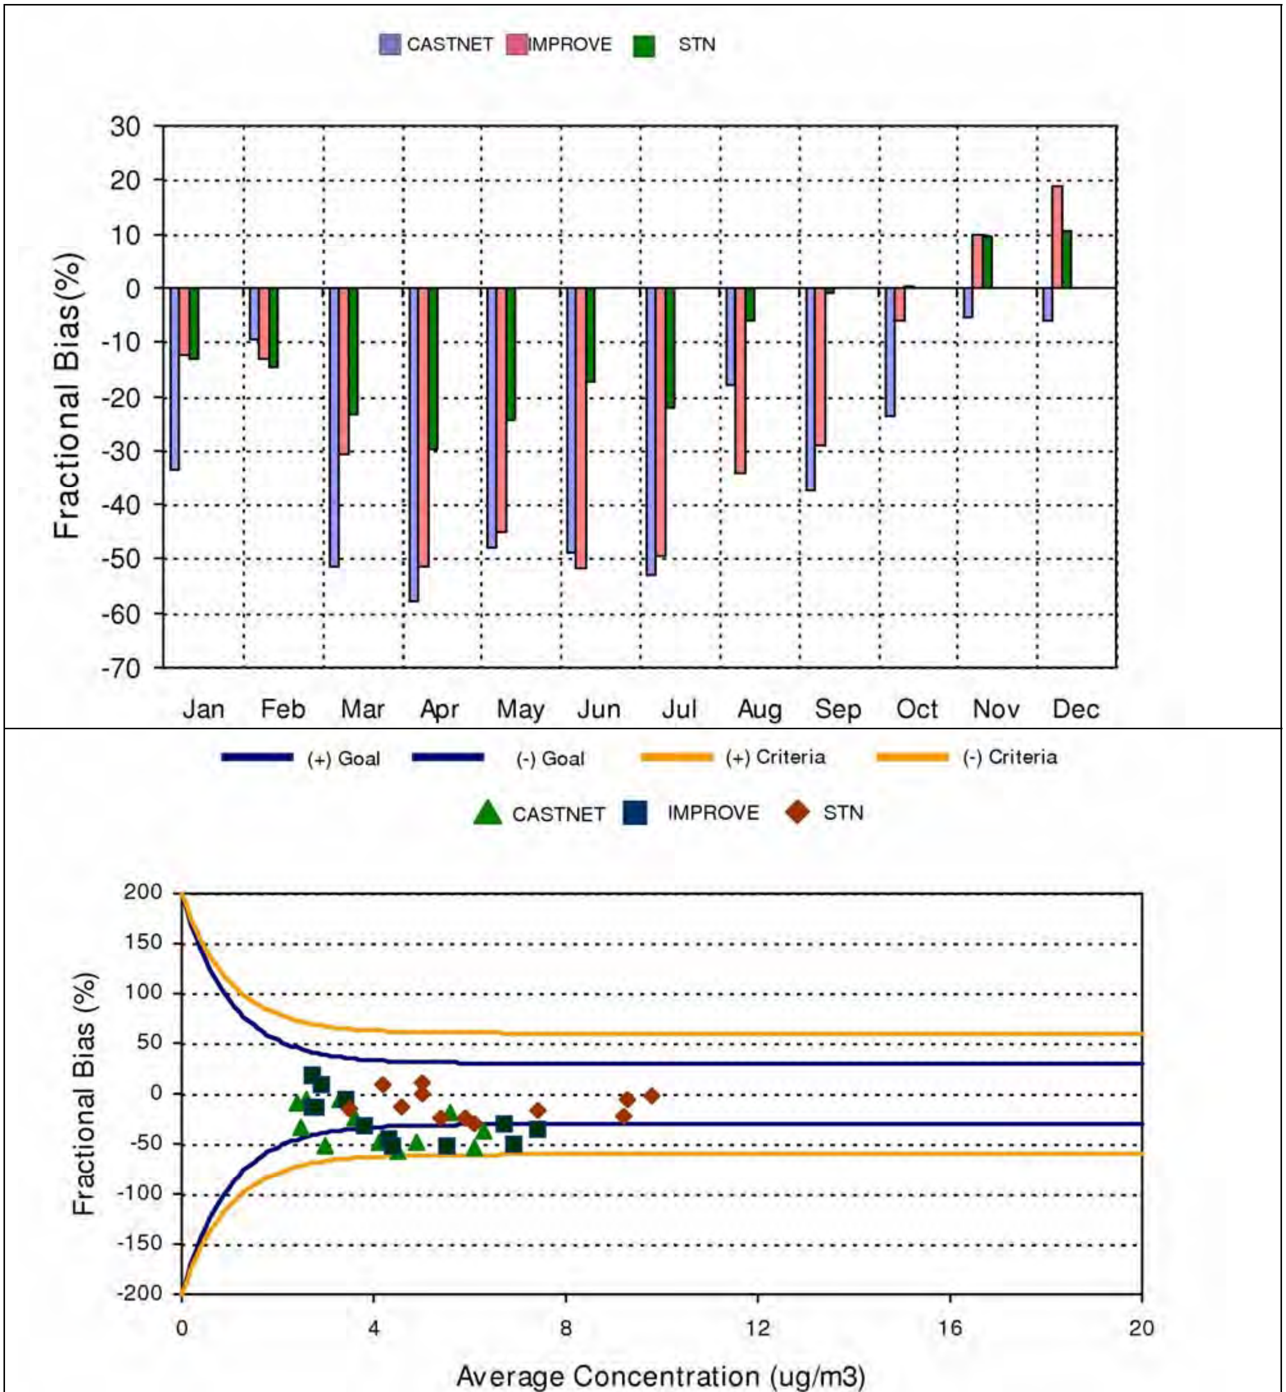

Figure 3-1. Monthly fractional bias (%) for sulfate (SO4) across the CENRAP region for the CMAQ 2002 36 km Base F base case simulation.

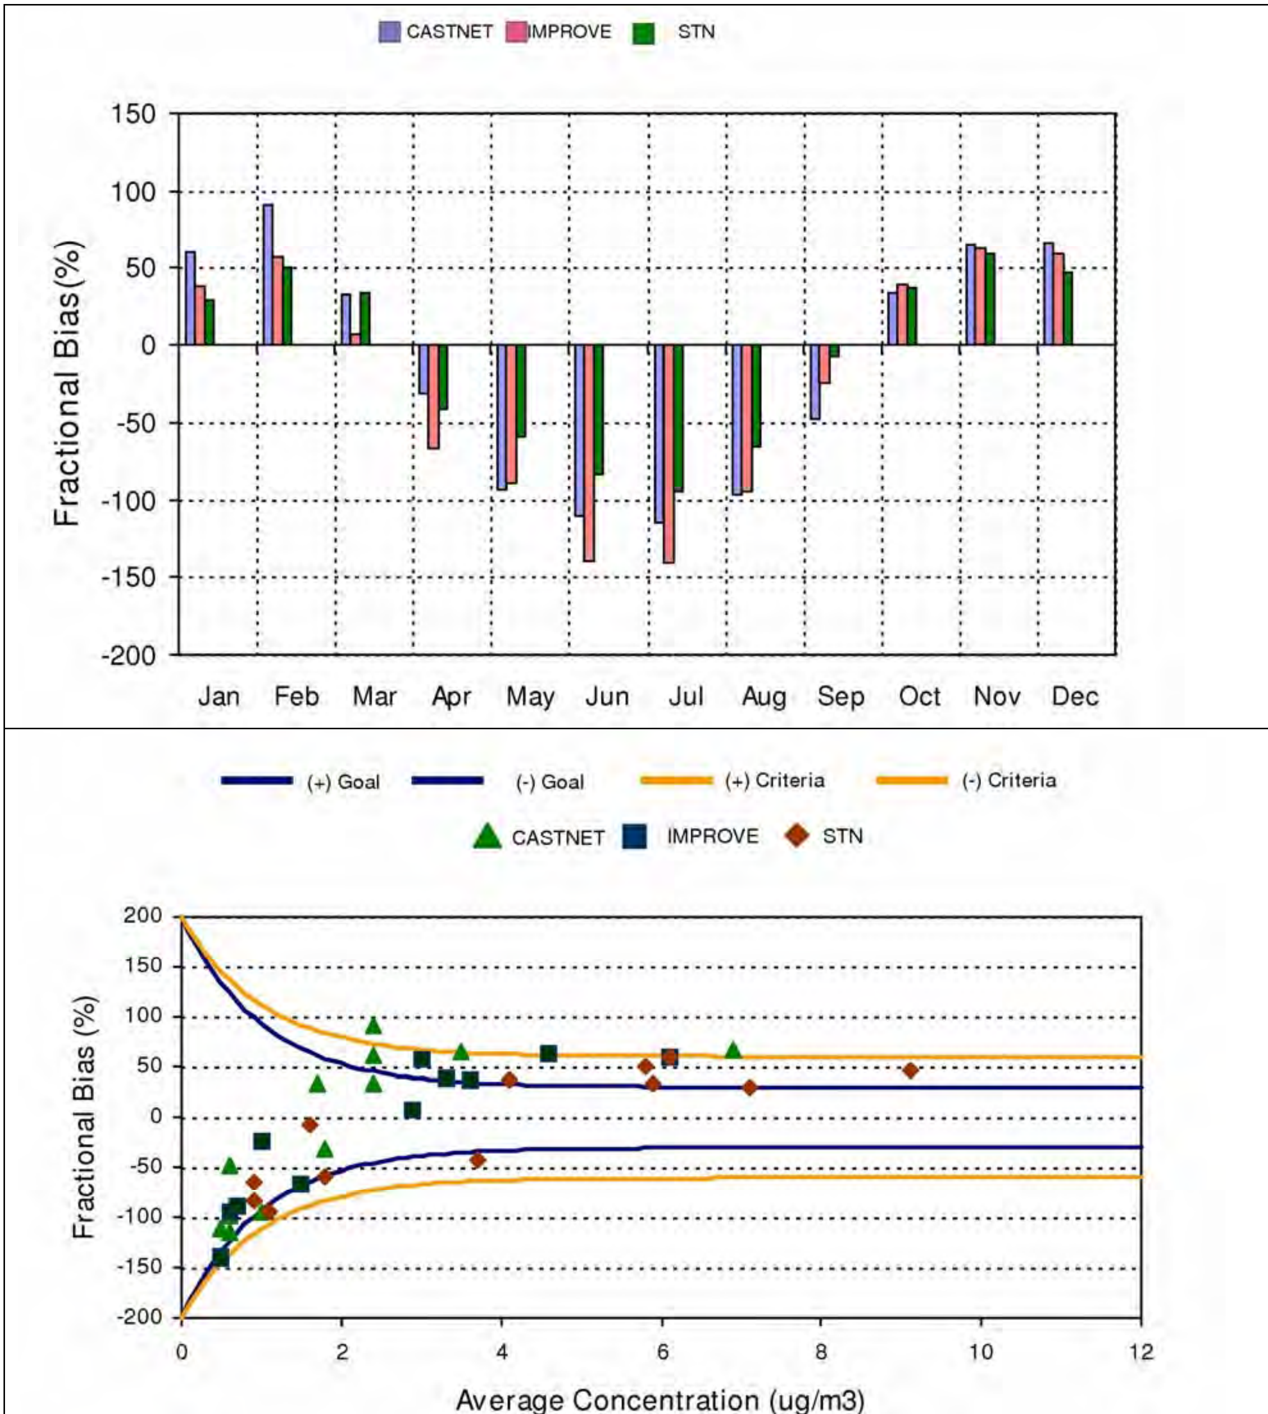

Figure 3-2. Monthly fractional bias (%) for nitrate (NO3) across the CENRAP region for the CMAQ 2002 36 km Base F base case simulation.

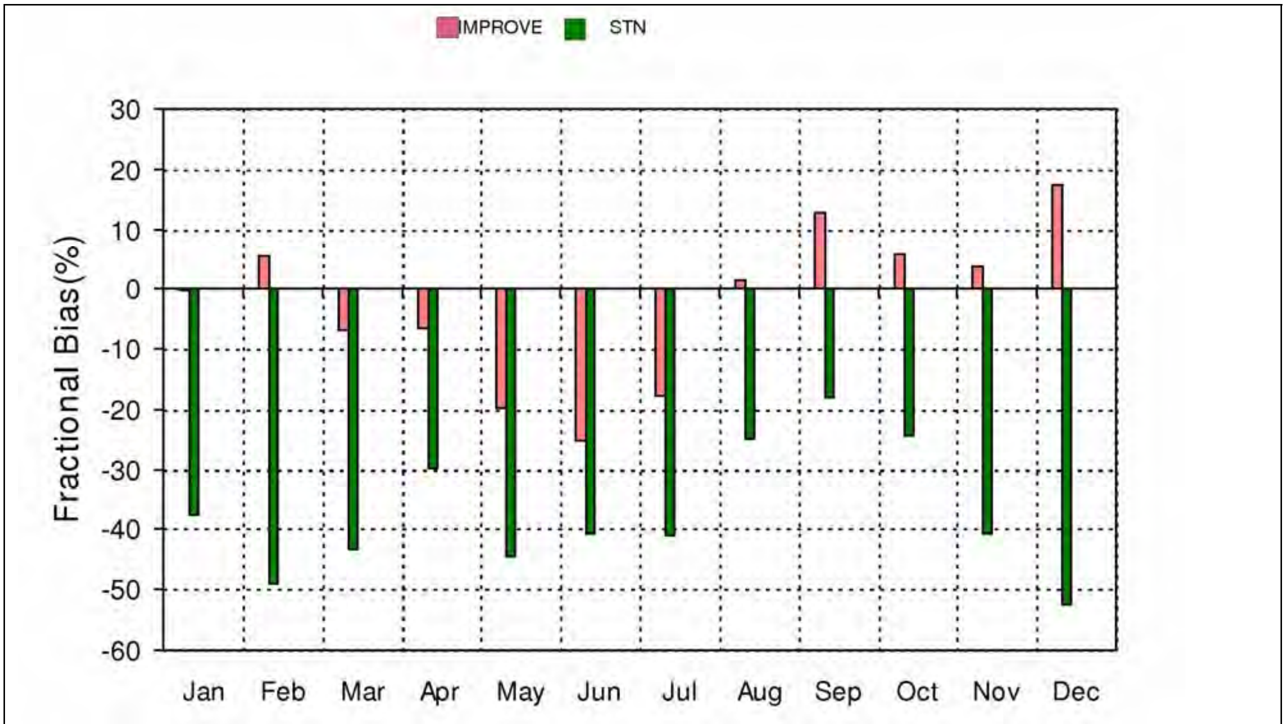

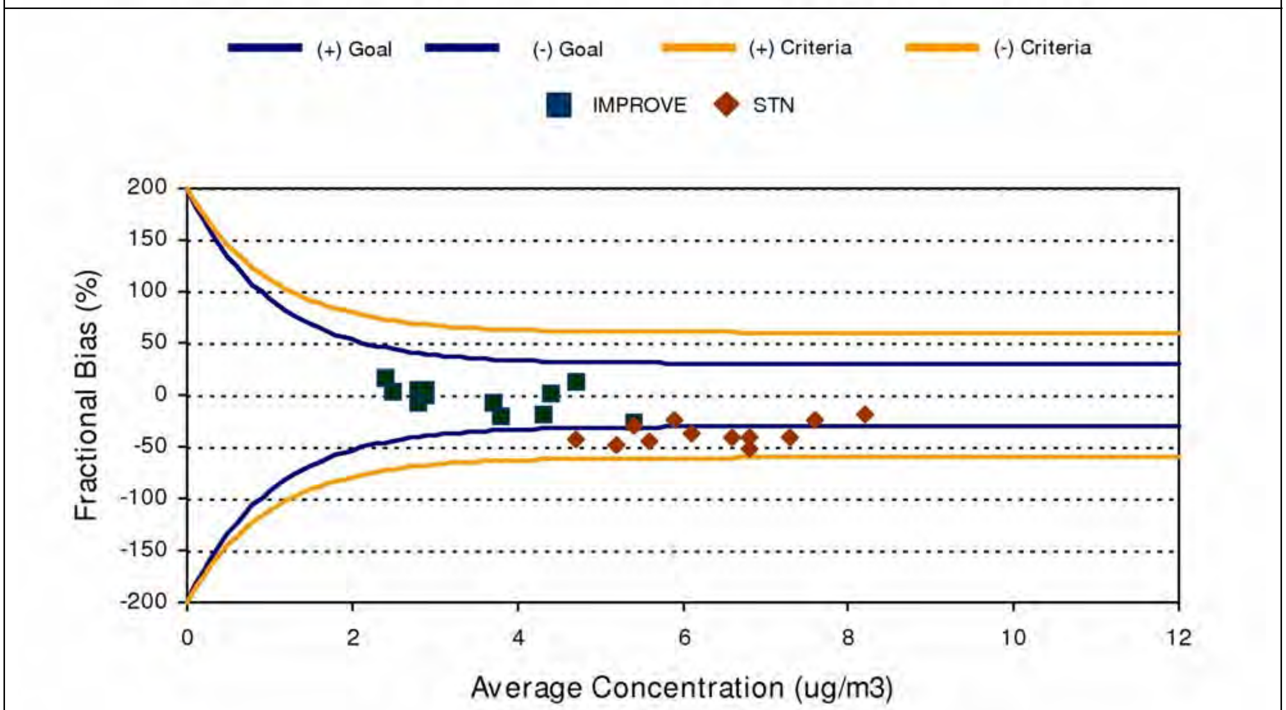

Figure 3-3. Monthly fractional bias (%) for organic matter carbon (OMC) across the CENRAP region for the CMAQ 2002 36 km Base F base case simulation.

3.5.4 Elemental Carbon (EC) Model Performance

The monthly average bias for EC across the IMPROVE and STN monitors in the CENRAP region are shown in Figure 3-4. The STN network exhibits small fractional bias year round, whereas the IMPROVE monitoring network exhibits a large underprediction bias in the summer months (-40% to -70%) and much smaller bias in the winter. The Bugle Plot puts the EC performance in context. The low EC concentrations at the IMPROVE sites results in bias values in the horn of the Bugle Plot. Thus, EC bias achieves the proposed PM performance goal for all months of the year.

3.5.5 Other $PM_{2.5}$ (Soil) Model Performance

Figure 3-5 displays the monthly variation in the Soil fractional bias using IMPROVE measurements in the CENRAP region. During the winter months, the model exhibits a very large (> 100%) overestimation bias. With the exception of July, the summer monthly bias is toward a slight overprediction but generally less than 20%. The July underestimation bias appears to be driven by impacts of high Soil values from wind blown dust events (e.g., see July 2002 discussion in Appendix C). The Bugle Plot indicates that the summer Soil performance achieves the PM performance goal, a few months in the Spring/Fall period fall between the performance goal and criteria and the winter Soil performance exceeds the model performance criteria. Thus, the Soil performance is a cause for concern.

3.5.6 Coarse Mass (CM) Model Performance

The monthly average fractional bias values for CM are shown in Figure 3-6. In the winter the underprediction bias is typically in the -60% to -80% range. In the late Spring and Summer the underprediction bias ranges from -120% to -160%. As this underprediction bias is nearly systematic (i.e., an underprediction almost always occurs), then the fractional errors are the same magnitude as the bias.

The Bugle Plots clearly show that the CM model performance is a problem. The monthly bias exceeds both the performance goal and criteria for almost every month of the year.

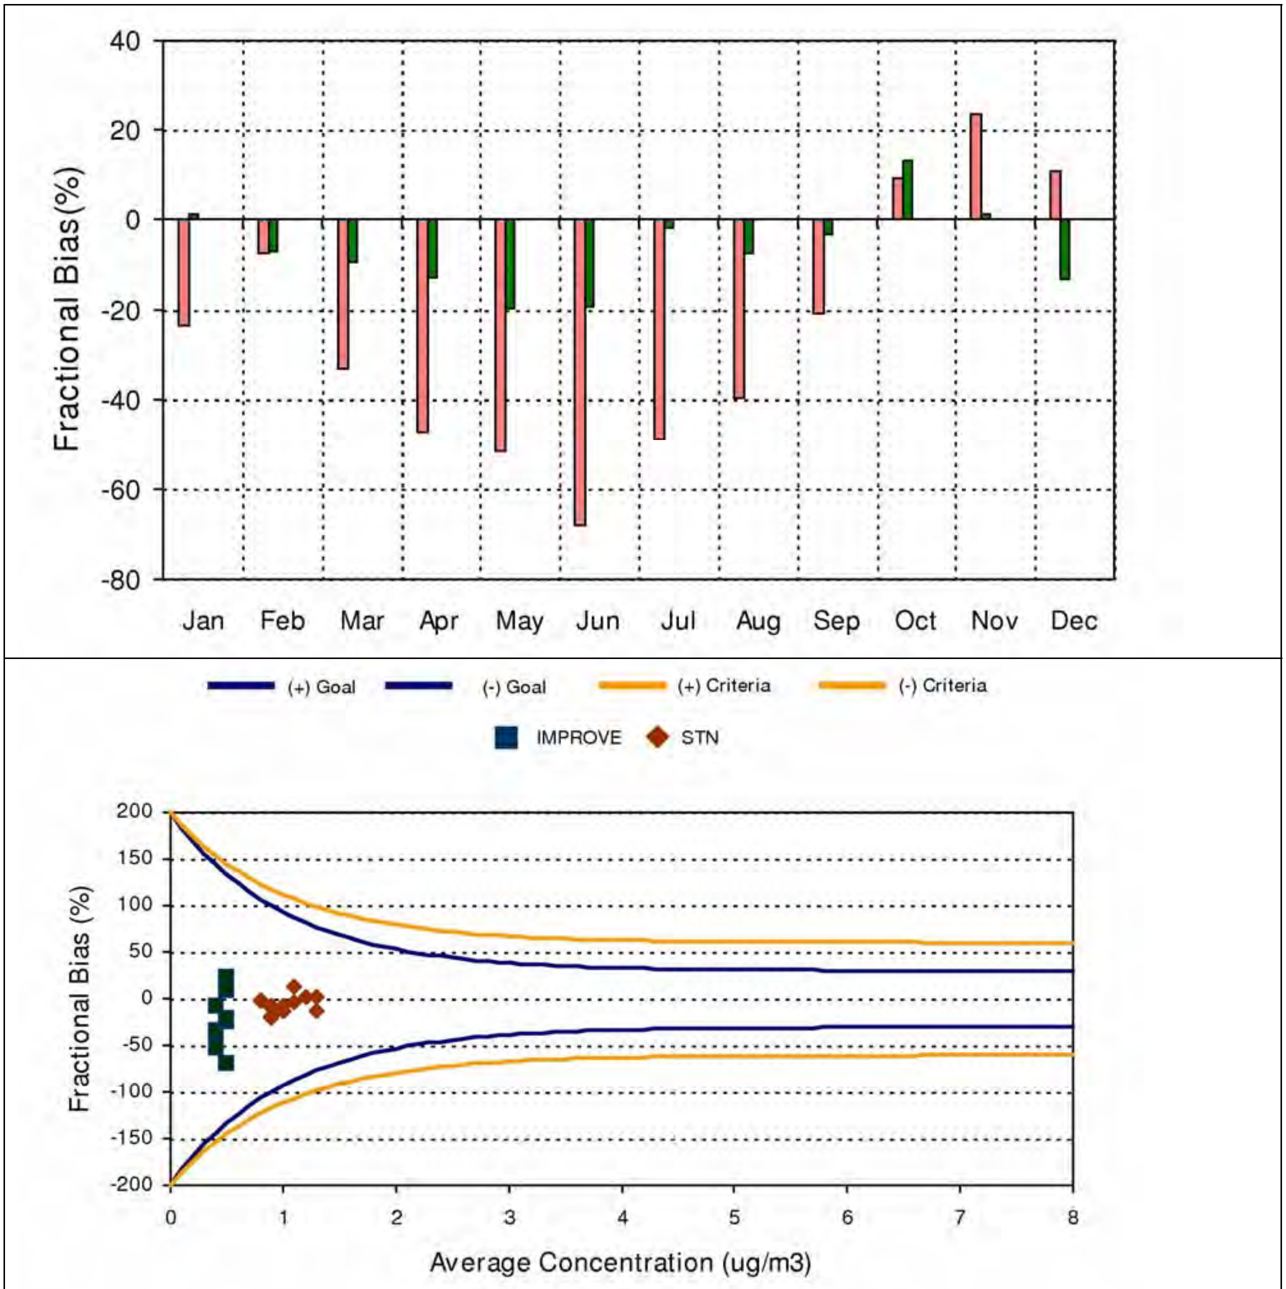

Figure 3-4. Monthly fractional bias (%) for elemental carbon (EC) across the CENRAP region for the CMAQ 2002 36 km Base F base case simulation.

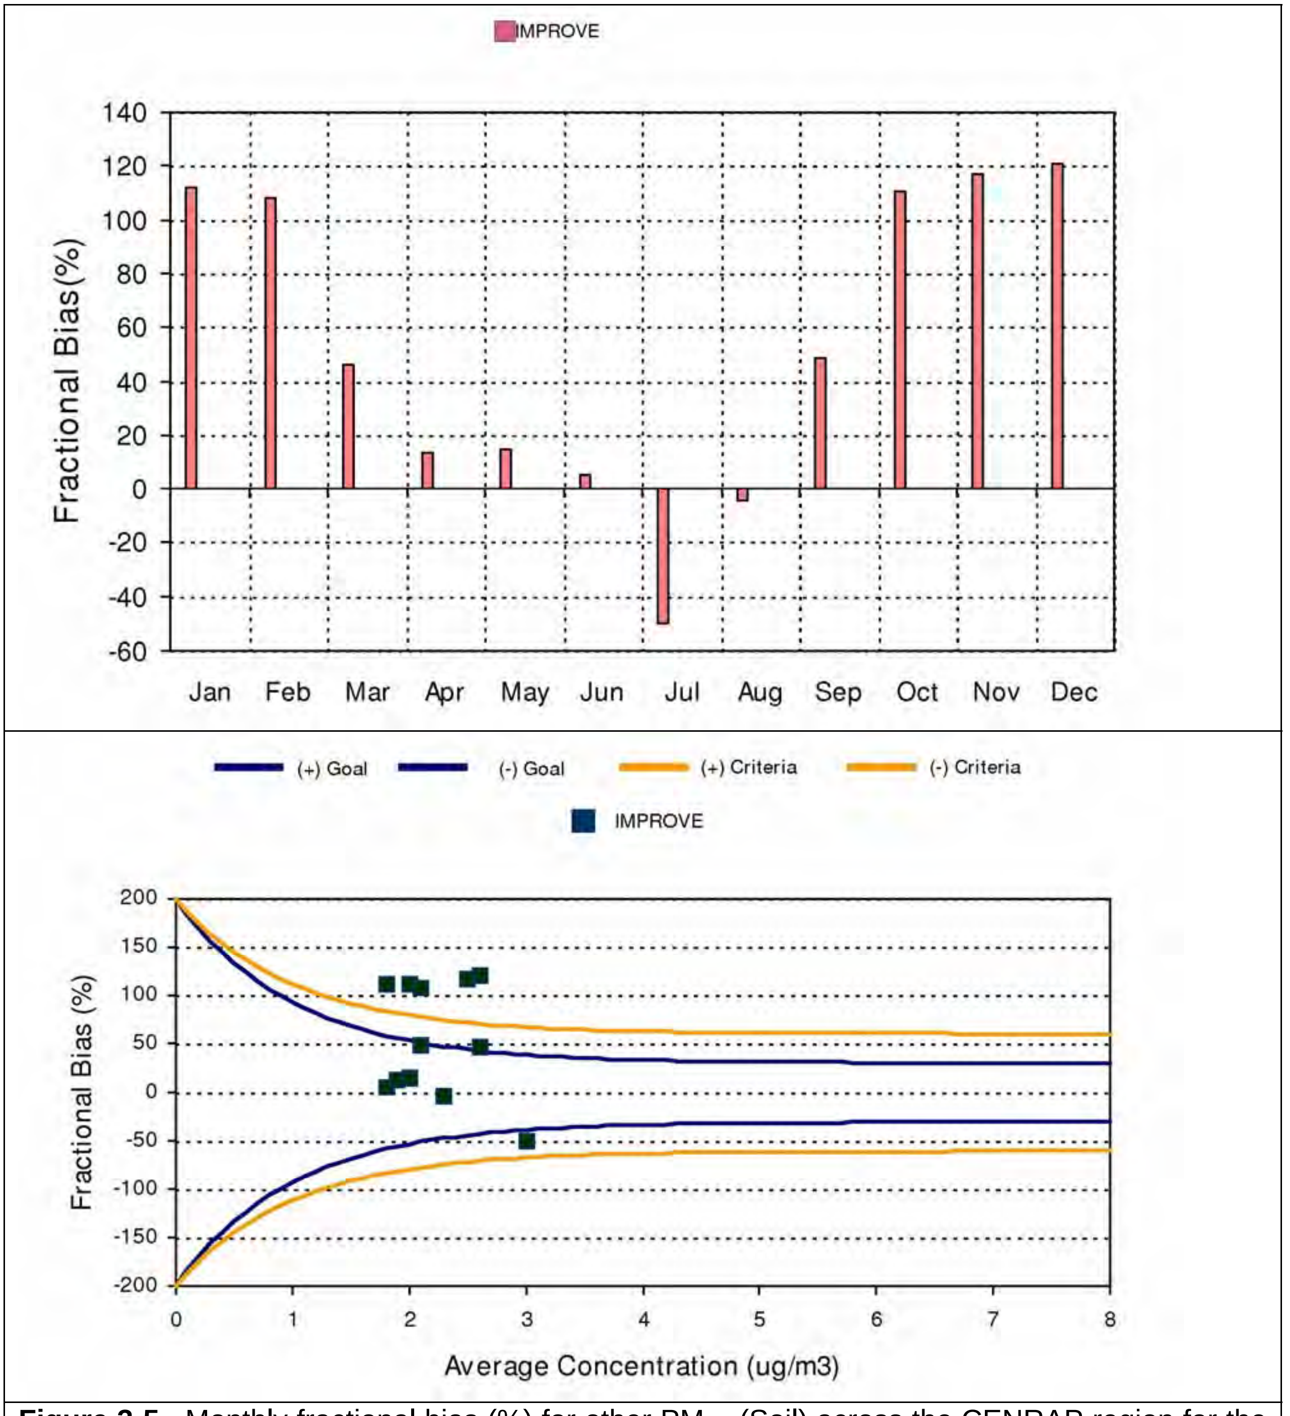

Figure 3-5. Monthly fractional bias (%) for other $PM_{2.5}$ (Soil) across the CENRAP region for the CMAQ 2002 36 km Base F base case simulation.

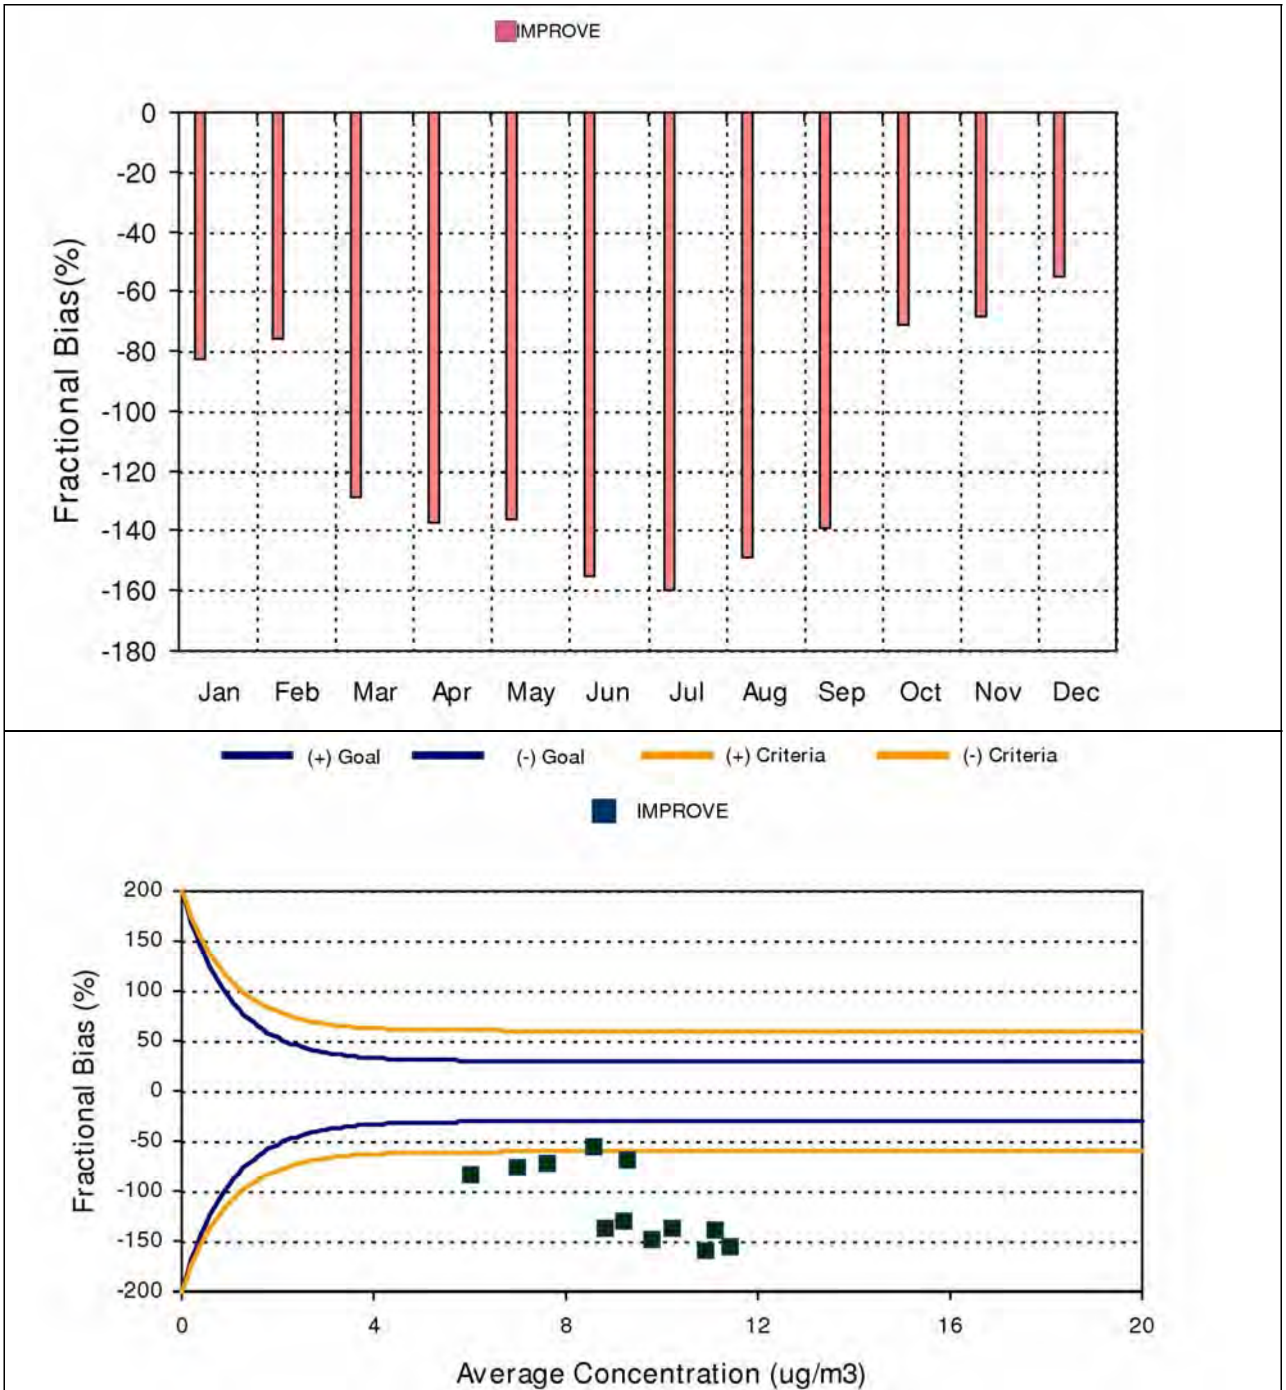

Figure 3-6. Monthly fractional bias (%) for coarse mass (CM) across the CENRAP region for the CMAQ 2002 36 km Base F base case simulation.

3.6 Diagnostic Model Performance Evaluation

The CASTNet and AQS networks also measure gas-phase species that are PM precursor or related species. The diagnostic evaluation of the 2002 36 km Base F CMAQ base case simulation for these compounds and the four seasonal months are presented in Appendix C. The displays for January are provided below as an example; the reader is referred to Appendix C for the rest of the monthly displays.

The CASTNet network measures weekly average samples of SO2, SO4, NO2, HNO3, NO3 and NH4. The AQS network collects hourly measurements of SO2, NO2, O3 and CO. A comparison of the SO2 and SO4 performance provides insight into whether the SO4 formation rate may be too slow or fast. For example, if SO4 is underestimated and SO2 is overestimated that may indicate chemical conversion rates that are too slow. Analyzing the performance for SO4, HNO3, NO3, Total NO3 and NH4 provides insight into the equilibrium of these species. For example, if Total NO3 performs well but HNO3 and NO3 do not, then there may be issues associated with the partitioning between the gaseous and particulate phases of nitrate. Causes for incorrect HNO3/NO3 partitioning could include inadequate ammonia emissions and/or poorly characterized meteorological conditions (e.g., temperature).

3.6.1 Diagnostic Model Performance in January 2002

In January, SO2 is overstated across both the CASTNet and AQS sites with fractional bias values of 38% (Figure 3-7) and 31% (Figure 3-8), respectively. SO4 is understated by -34% across the CASTNet monitors (Figure 3-7) and -12% and -13% for the IMPROVE and STN networks (Figure C-4a). Wet SO4 deposition is also overstated in January (+40%, Figure C-4a). Given that SO2 emissions are well characterized, these results suggest that the January SO4 underestimation may be partly due to understated transformation rates of SO2 to SO4 and overstated wet SO4 deposition.

Total NO3 is overestimated by 35% on average across the CASTNet sites in the CENRAP region in January (Figure 3-7). HNO3 is underestimated (-34%) and particle NO3 is overestimated (+61%) suggesting there are gas/particle equilibrium issues. An analysis of the time series of the four CASTNet stations reveals that NO3, HNO3 and NH4 performance is actually very reasonable at the west Texas site and the HNO3 underestimation and NO3 overestimation bias is coming from the east Kansas, central Arkansas and northern Minnesota CASTNet sites (see Figure C-3 for site locations). One potential contributor for this performance problem could be overstated NH3 emissions. However, the Total NO3 overestimation bias suggests that the model estimated NOx oxidation rate may be too high in January.

The SO2, NO2, O3 and CO performance across the AQS sites in January is shown in Figure 3-8. The AQS monitoring network is primarily an urban-oriented network. So, it is not surprising that the model is underestimating concentrations of primary emissions when a 36 km grid is used. NO2 is underestimated by approximately 5%, and CO by approximately 67%. Ozone is also underestimated on average, especially the maximum values above 60 ppb.

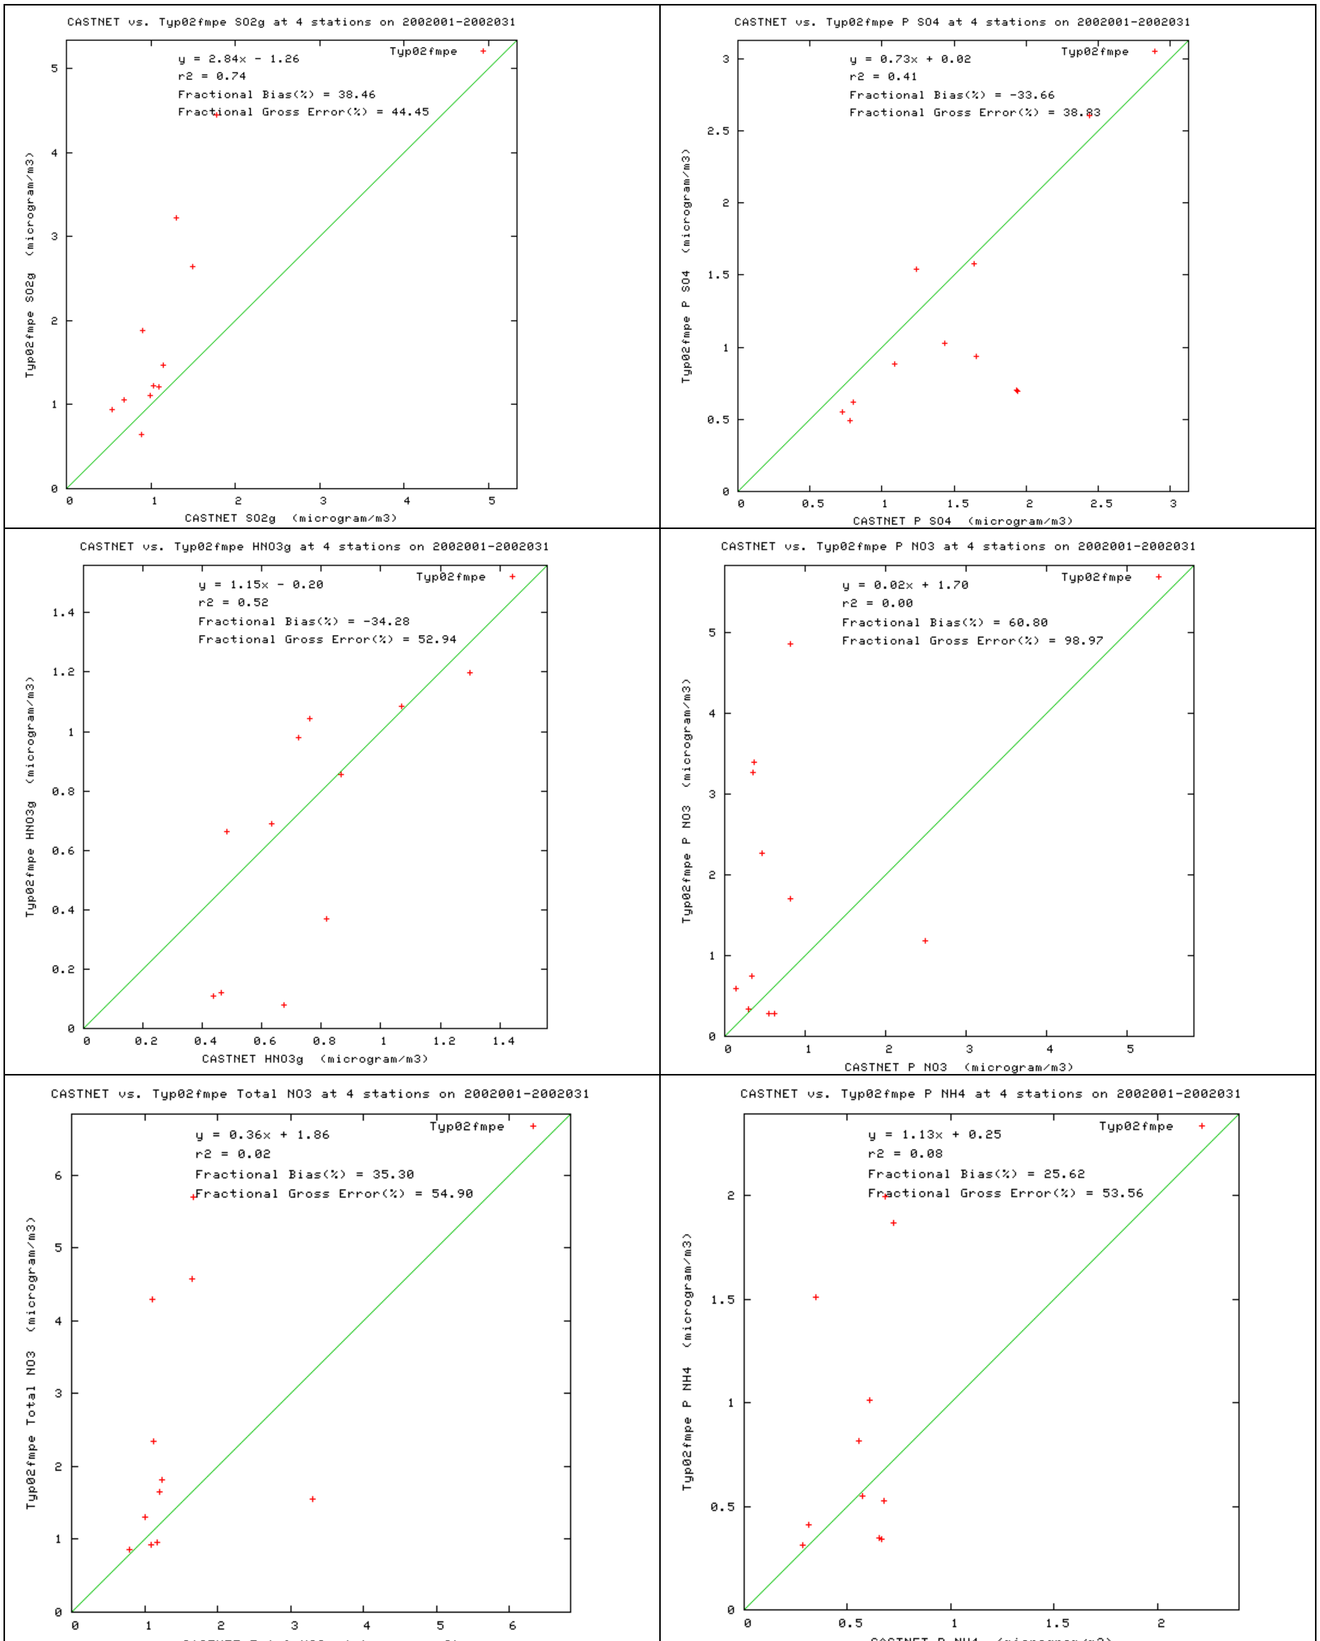

Figure 3-7. January 2002 performance at CENRAP CASTNet sites for SO2 (top left), SO4 (top right), HNO3 (middle left), NO3 (middle right), Total NO3 (bottom left) and NH4 (bottom right).

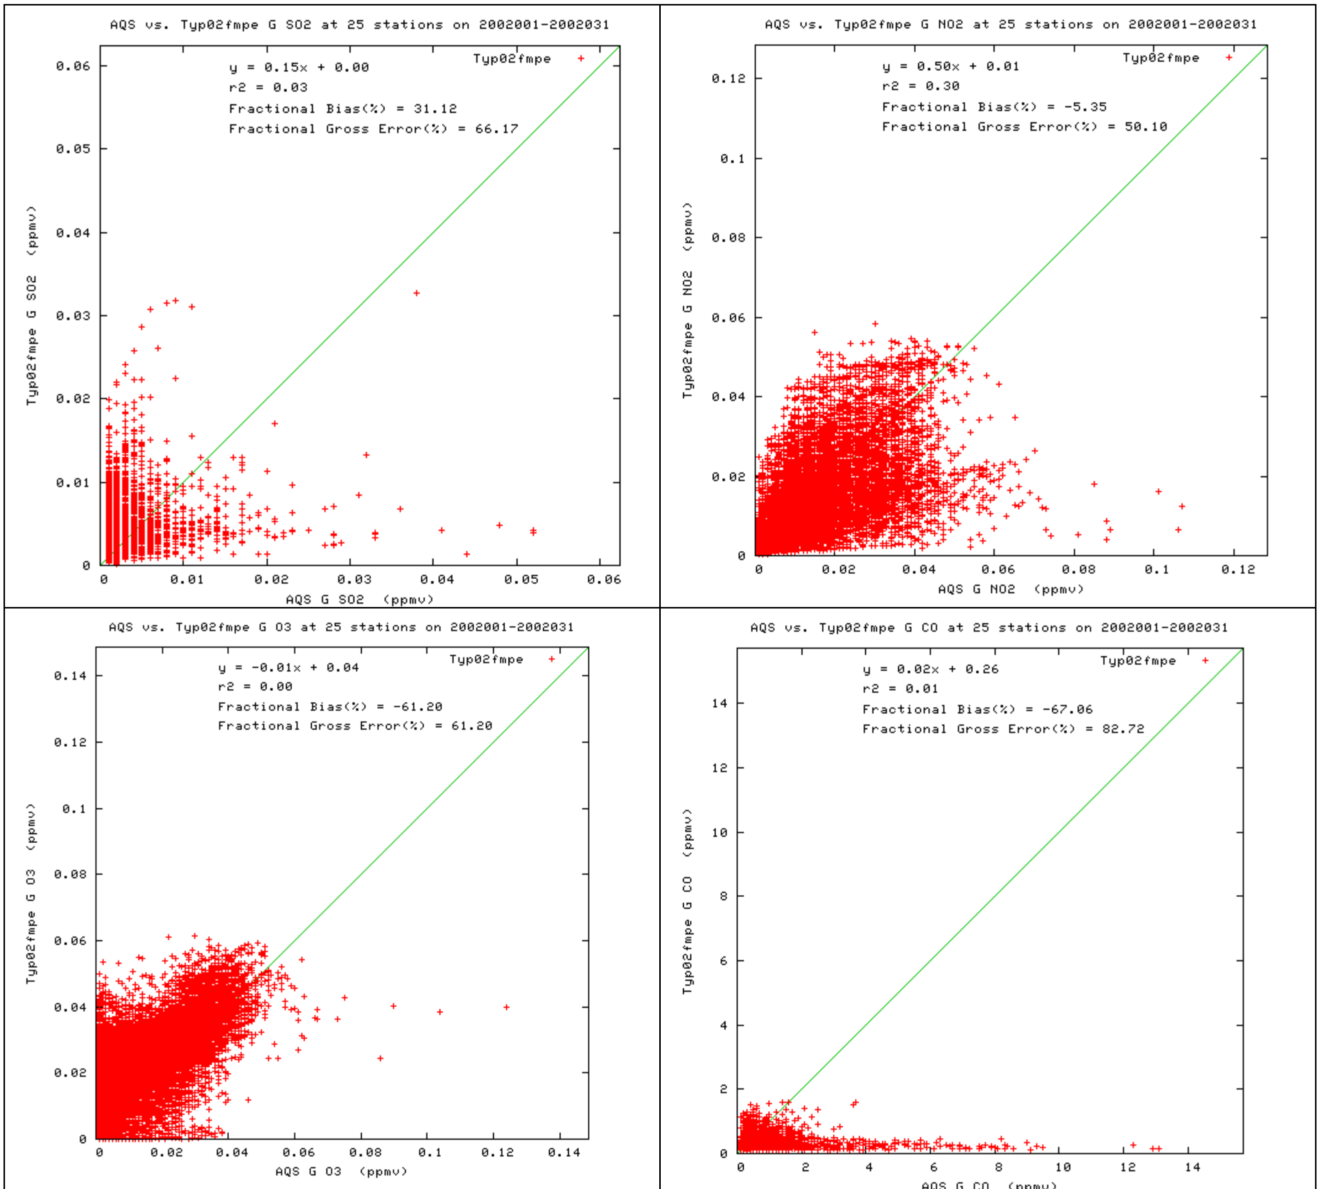

Figure 3-8. January 2002 performance at CENRAP AQS sites for SO2 (top left), NO2 (top right), O3 (bottom left) and CO (bottom right).

3.6.2 Diagnostic Model Performance In April

In April there is an average SO2 overestimation bias across the CASTNet (+15%) and underestimation bias across the AQS (-10%) networks (Figures C-42 and C-43). SO4 is underestimated across all networks by -30% to -58% (Figure C-5a). The wet SO4 deposition bias is near zero. Both SO2 and SO4 are underestimated at the west Texas CASTNet monitor in April suggesting SO2 emissions in Mexico are likely understated.

The HNO3 performance in April is interesting with almost perfect agreement except for 5 modeled-observed comparisons that drives the average underprediction bias of -29% (Figure C-42). On Julian Day 102 there is high HNO3 at the MN, KS and OK CASTNet sites that is not captured by the model. Given that HNO3, NO3 and Total NO3 are all underestimated by about the same amount (-30%), then part of the underestimation bias is likely due to too slow oxidation of NOx.

There is a lot of scatter in the NO2 and O3 performance that is more or less centered on the 1:1 line of perfect agreement with bias values of -8% and -21%, respectively (Figure C-43). CO is underestimated by -72% with the model unable to predict CO concentrations above 1 ppm due to the use of the coarse 36 km grid spacing. Mobile sources produce a vast majority of the CO emissions. So, AQS monitors for CO compliance are located near roadways, which are not simulated well using a 36 km grid.

3.6.3 Diagnostic Model Performance In July

In July SO2 is slightly underestimated across the CASTNet (-5%) and AQS (-12%) networks (Figures C-44 and C-45). SO4 is more significantly underestimated across all networks (-22% to -53%, as shown in Figure C-6a). Since wet deposition SO4 is also underestimated, it is unclear why all sulfur species are underestimated.

The nitrate species are also all underestimated with the Total NO3 bias (-56%) being between the HNO3 bias (-35%) and NO3 bias (-115%). The modeled NO3 values are all near zero with little correlation with the observations, whereas the observed HNO3 and Total NO3 is tracked well with correlation coefficients of 0.74 and 0.76. These results suggest that the July NO3 model performance problem is partly due to insufficient formation of Total NO3, but mainly due to incorrect partitioning of the Total NO3.

Again, there is abundant scatter in the AQS NO2 scatter plot for July (Figure C-45) resulting in a low bias (0%) but high error (65%). Ozone performance also exhibits a low bias (-15%) and error (20%), but the model is incapable of simulating ozone above 100 ppb. Although CO performance in July is better than the previous months, it still has a large underestimation bias of 82%.

3.6.4 Diagnostic Model Performance In October

SO2 is overstated in October across the CASTNet (+28%) and AQS (+33%) sites (Figures C-46 and C-47). Although SO4 is understated across the CASTNet sites (-24%), the bias across the IMPROVE (-6%) and STN (0%) sites are near zero (Figure C-7a).

Performance for HNO3 is fairly good with a low bias (+12%) and error (30%). But NO3 is overstated (+34%) leading to an overstatement of Total NO3 (+37%). The overstatement of NO3 leads to an overstatement of NH4 as well (Figure C-46)

As seen in the other months, NO2 exhibits a lot of scatter resulting in a low correlation (0.22) and high error (61%) but low bias (12%). The model tends to underpredict the high and overpredict the low O3 observations resulting in a -29% bias and low correlation coefficient. CO is also underpredicted (-76%) for the reasons discussed previously.

3.7 Performance at CENRAP Class I Areas for the Worst and Best 20 Percent Days

In this section, and in section C.5 of Appendix C, we present the results of the model performance evaluation at each of the CENRAP Class I areas for the worst and best 20 percent days. Performance on these days is critical since they are the days used in the 2018 visibility projections discussed in Chapter 4. For each Class I area we compared the predicted and observed extinction of the worst and best 20 percent days below. In Appendix C the PM species-specific extinction is also compared for the worst 20 percent days.

3.7.1 Caney Creek (CACR) Arkansas

The ability of the CMAQ model to estimate visibility extinction at the CACR Class I area on the 2002 worst and best 20 percent days is provide in Figures 3-9 and C-48. On most of the worst 20 percent days at CACR total extinction is dominated by SO4 extinction with some extinction due to OMC. On four of the worst 20 percent days extinction is dominated by NO3. The average extinction across the worst 20 percent days is underestimated by -33% (Figure 3-9), which is primarily due to a -51% underestimation of SO4 extinction combined with a 6% overestimation of NO3 extinction (Figure C-48). Performance for OMC extinction at CACR on the worst 20 percent days is pretty good with a -20% bias and 36% error. EC extinction is systematically underestimated. Soil extinction has low bias (-19%) buts lots of scatter and high error (74%), while CM extinction is greatly underestimated (bias of -153%).

On the best 20 percent days at CACR the observed extinction ranges from 20 to 40 Mm^{-1}. Whereas, the modeled extinction has a much larger range from 15 to 120 Mm^{-1}. Much of the modeled overestimation of total extinction on the best 20% days (+44% bias) is due to NO3 overestimation (+94% bias).

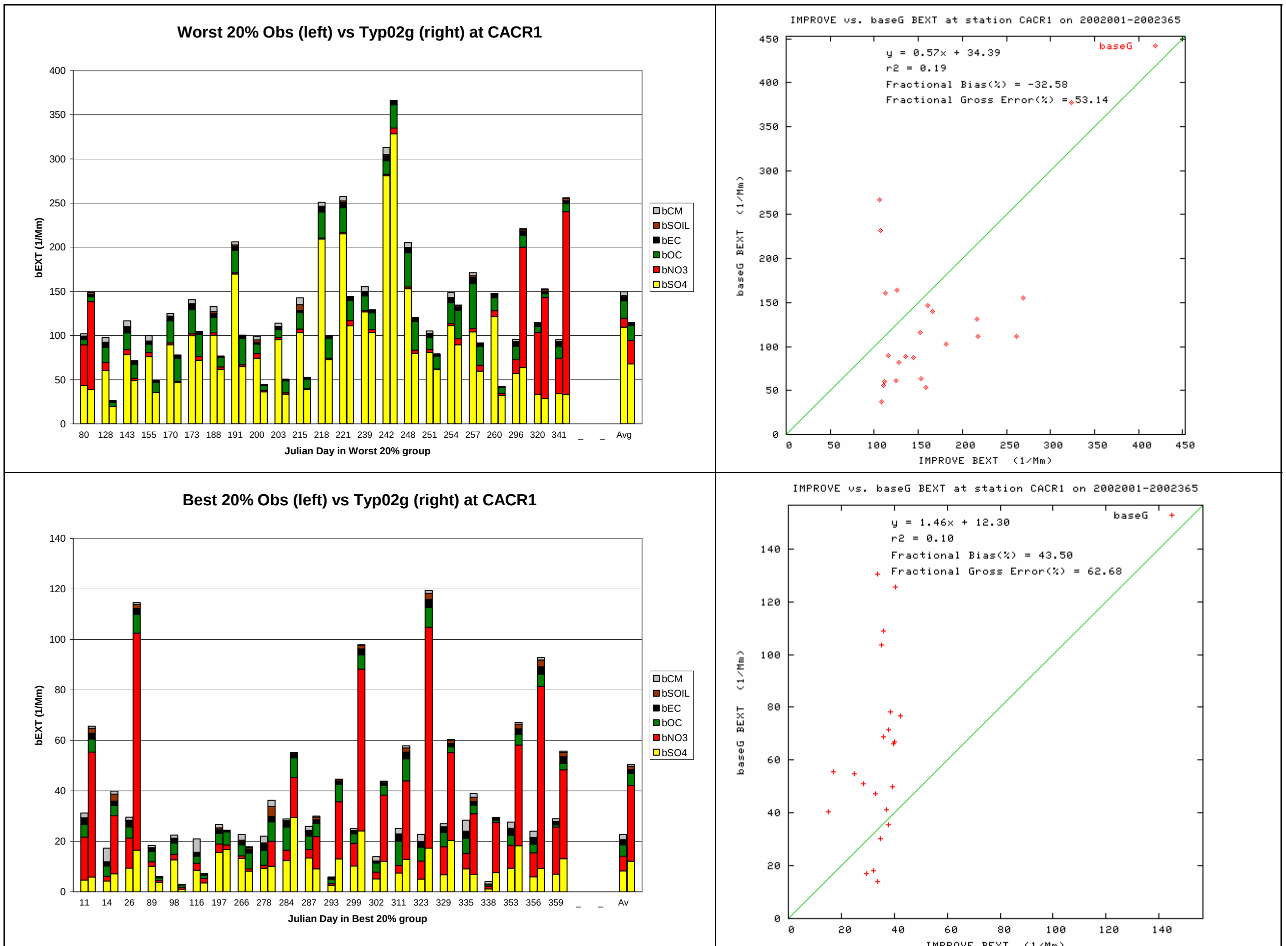

Figure 3-9. Daily extinction model performance at Caney Creek (CACR), Arkansas for the worst (top) and best (bottom) 20 percent days during 2002.

3.7.2 Upper Buffalo (UPBU) Arkansas

Model performance at the UPBU Class I area for the worst and best 20 percent days is shown in Figures 3-10 and C-49. On most of the worst 20 percent days at UPBU, visibility impairment is dominated by SO4, although there are also two high NO3 days. The model underestimates the average of the total extinction on the worst 20 percent days at UPBU by -40% (Figure 3-10), which is due to an underestimation of extinction due to SO4, OMC and CM by -46%, -33% and -179%, respectively.

On the best 20 percent days at UPBU, the model performs reasonably well with a low bias (2%) and error (42%). But again, the model has a much wider range in extinction values across the best 20 percent days (15 to 120 Mm^{-1}) than observed (20 to 45 Mm^{-1}). There are five days in which the modeled NO3 overprediction is quite severe and when those days are removed the range in the modeled and observed extinction on the best 20 percent days is quite similar to the observed, although the model gets much cleaner on the very cleanest modeled days.

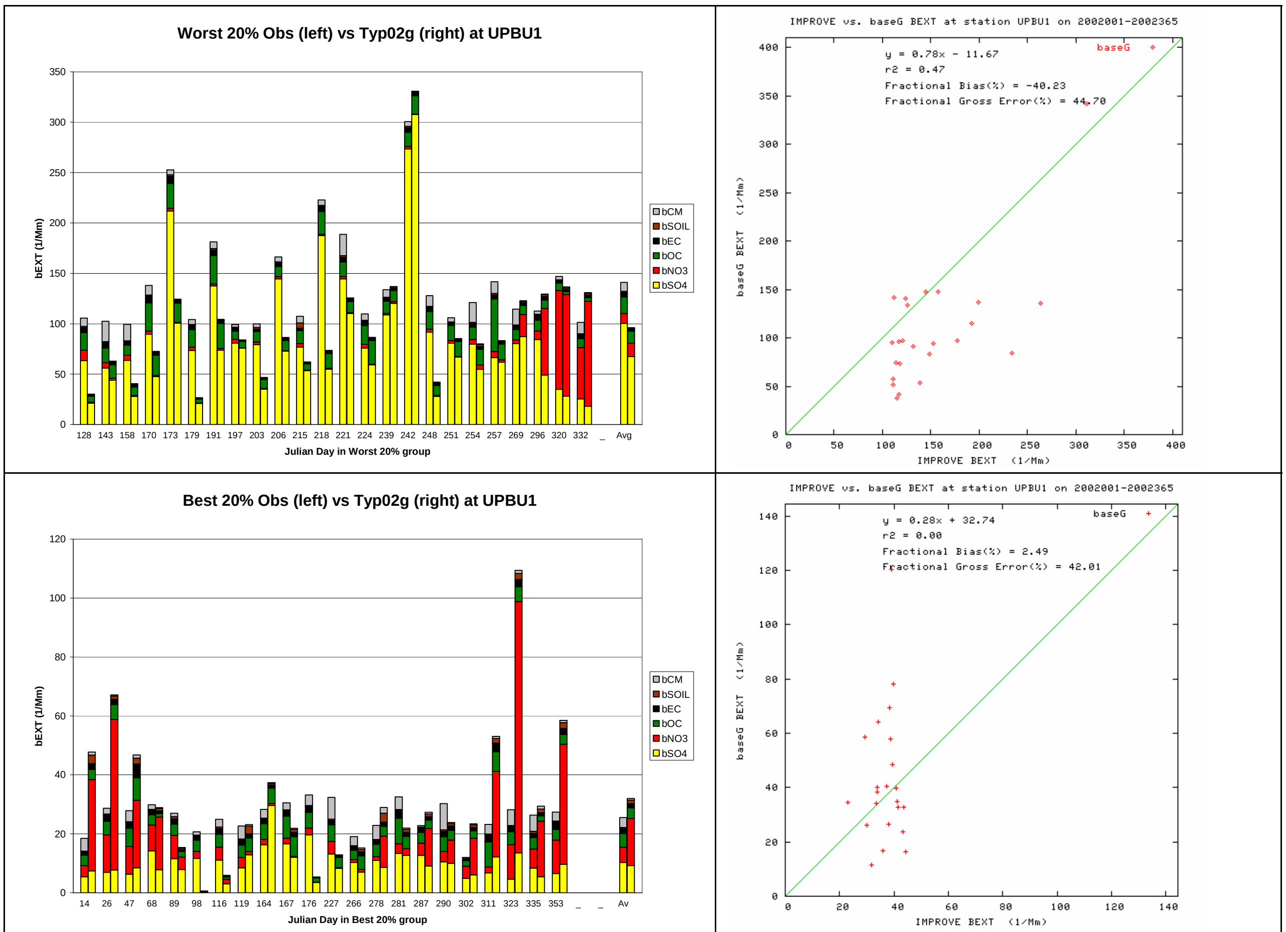

Figure 3-10. Daily extinction model performance at Upper Buffalo (UPBU), Arkansas for the worst (top) and best (bottom) 20 percent days during 2002.

3.7.3 Breton Island (BRET), Louisiana

The observed total extinction on the worst 20 percent days at Breton Island is underestimated by -71% (Figure 3-11), which is due to an underestimation of each component of extinction (Figure C-50) by from -50% to -70% (SO4, OMC and Soil) to over -100% (EC and CM). The observed extinction on the worst 20 percent days ranges from 90 to 170 Mm^{-1}, whereas the modeled values drop down to as low as approximately 15 Mm^{-1}. On the best 20 percent days the range of the observed and modeled extinction is similar (roughly 10 to 50 Mm^{-1}) that results in a reasonably low bias (-22%), but there is little agreement on which days are higher or lower resulting in a lot of scatter and high error (54%).

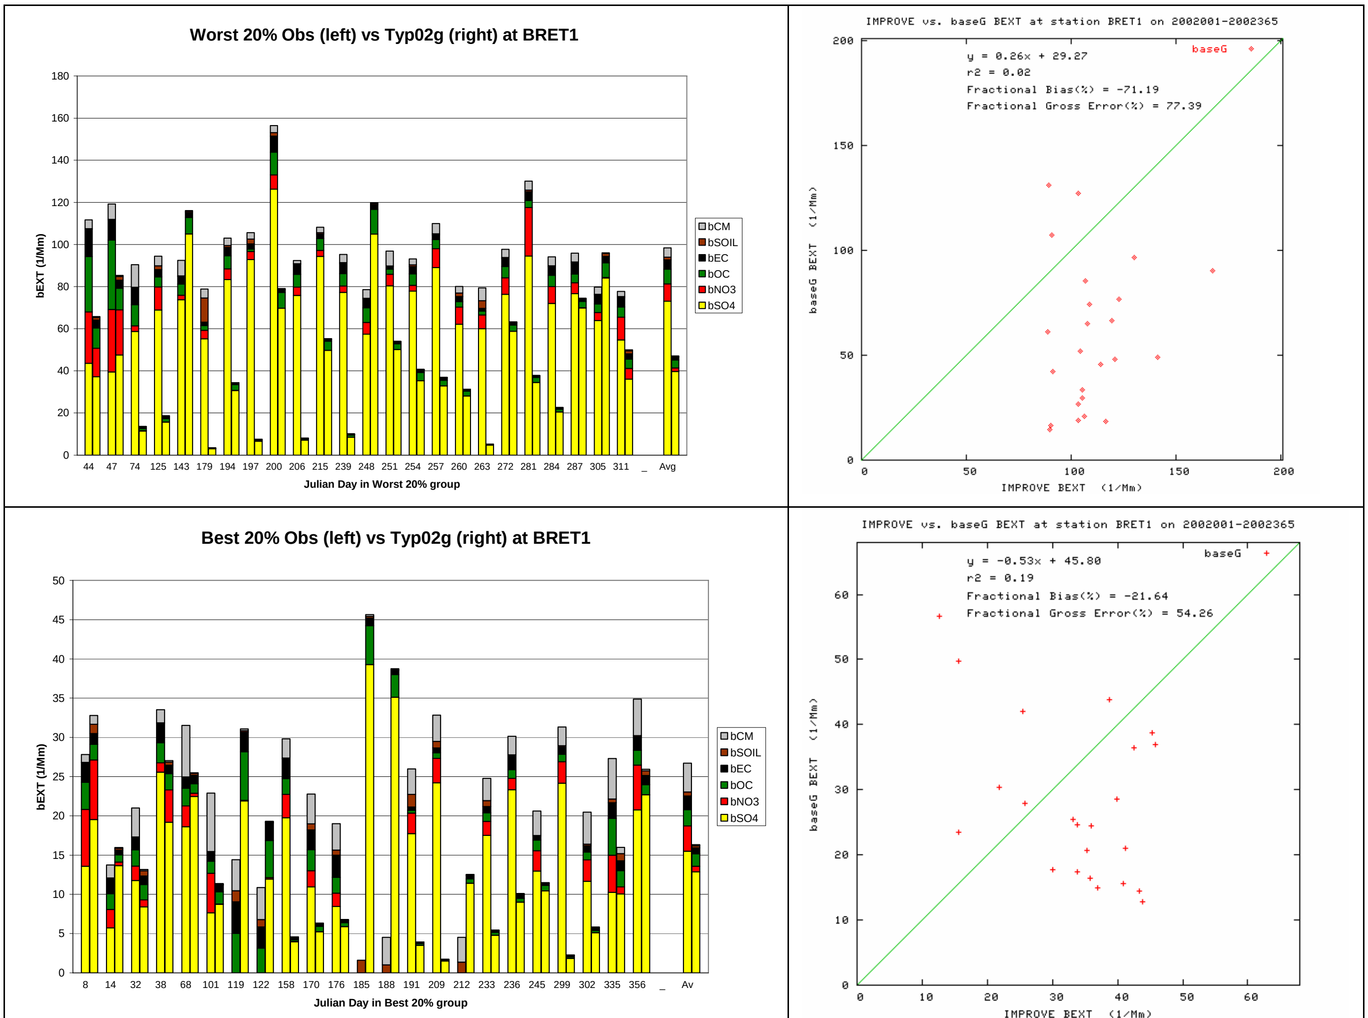

Figure 3-11. Daily extinction model performance at Breton Island (BRET), Louisiana for the worst (top) and best (bottom) 20 percent days during 2002.

3.7.4 Boundary Waters (BOWA), Minnesota

There are three types of days during the worst 20 percent days at BOWA: SO4 days, OMC days and NO3 days (Figure 3-12). The two high OMC days are likely fire impact events that the model captures to some extent on one day and not on the other. On the five high (> 20 Mm^{-1}) NO3 extinction days the model predicts the observed extinction well on three days and overestimates by a factor of 3-4 on the other two high NO3 days. SO4 is underestimated by -43% on average across the worst 20 percent days at BOWA.

With the exception of two days, the model reproduces the total extinction for the best 20 percent days at BOWA quite well with a bias and error value of +14% and 22% (Figure 3-12). Without these two days, the modeled and observed extinction both range between 15 and 25 Mm^{-1}.

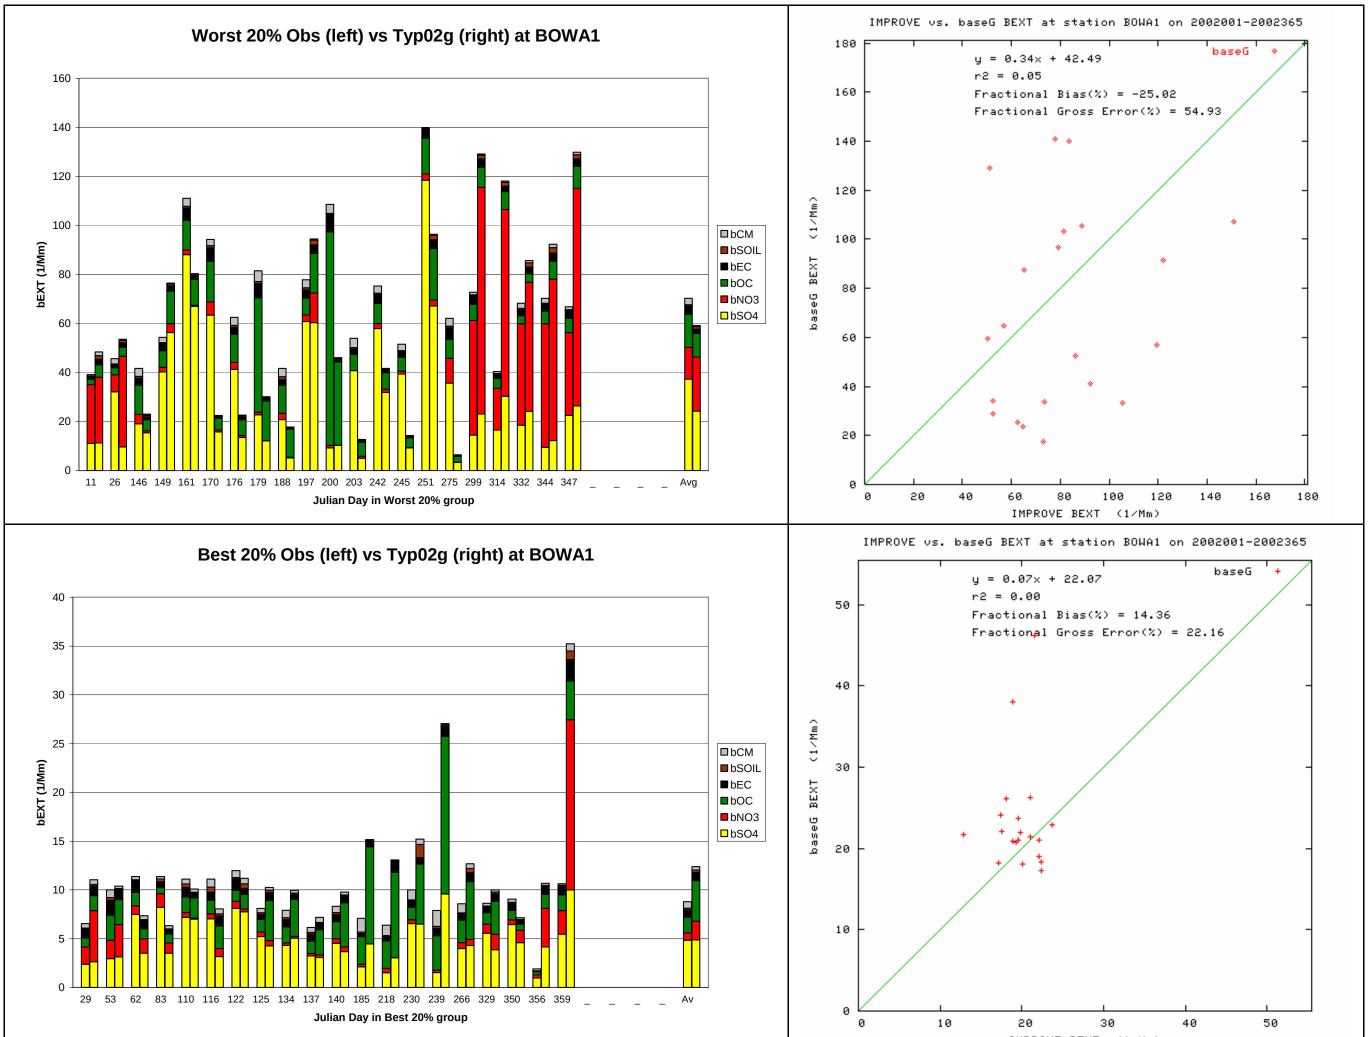

Figure 3-12. Daily extinction model performance at Boundary Waters (BOWA), Minnesota for the worst (top) and best (bottom) 20 percent days during 2002.

3.7.5 Voyageurs (VOYA) Minnesota

VOYA is also characterized by SO4, NO3 and OMC days (Figure 3-13). Julian Days 179 and 200 are high OMC days that were also high OMC days at BOWA again indicating impacts from fires in the area that is not fully captured by the model. SO4 and NO3 performance is fairly good and, without the fire days, OMC performance looks good as well (Figure C-52). On the best 20 percent days there is one day the modeled extinction is much higher than observed and a few others that are somewhat higher, but for most of the best 20 percent days the modeled extinction is comparable to the observed values.

Figure 3-13. Daily extinction model performance at Voyageurs (VOYA), Minnesota for the worst (top) and best (bottom) 20 percent days during 2002.

3.7.6 Hercules Glade (HEGL) Missouri

On most of the worst 20 percent days at HEGL the observed extinction ranges from 120 to 220 Mm^{-1} whereas model extinction ranges from 50 to 170 Mm^{-1} (Figure 3-14). However, there is one extreme day with extinction approaching 400 Mm^{-1} that the model does a very good job in replicating. Over all the days there is a modest underestimation bias in SO4 (-39%) and OMC (-39%) extinction, larger underestimation bias in EC (-62%) and CM (-118%) extinction and overestimation bias in Soil (+30%) extinction (Figure C-53).

On the best 20 percent days there is one day where the model overstates the observed extinction by approximately a factor of four and a handful of other days that the model overstates the extinction by a factor of 2 or so, but most of the days both the model and observed extinction sites are around 40 Mm^{-1} ±10 Mm^{-1}. On the best 20 percent days, when the observed extinction is overstated, it is due to overstatement of the NO3.

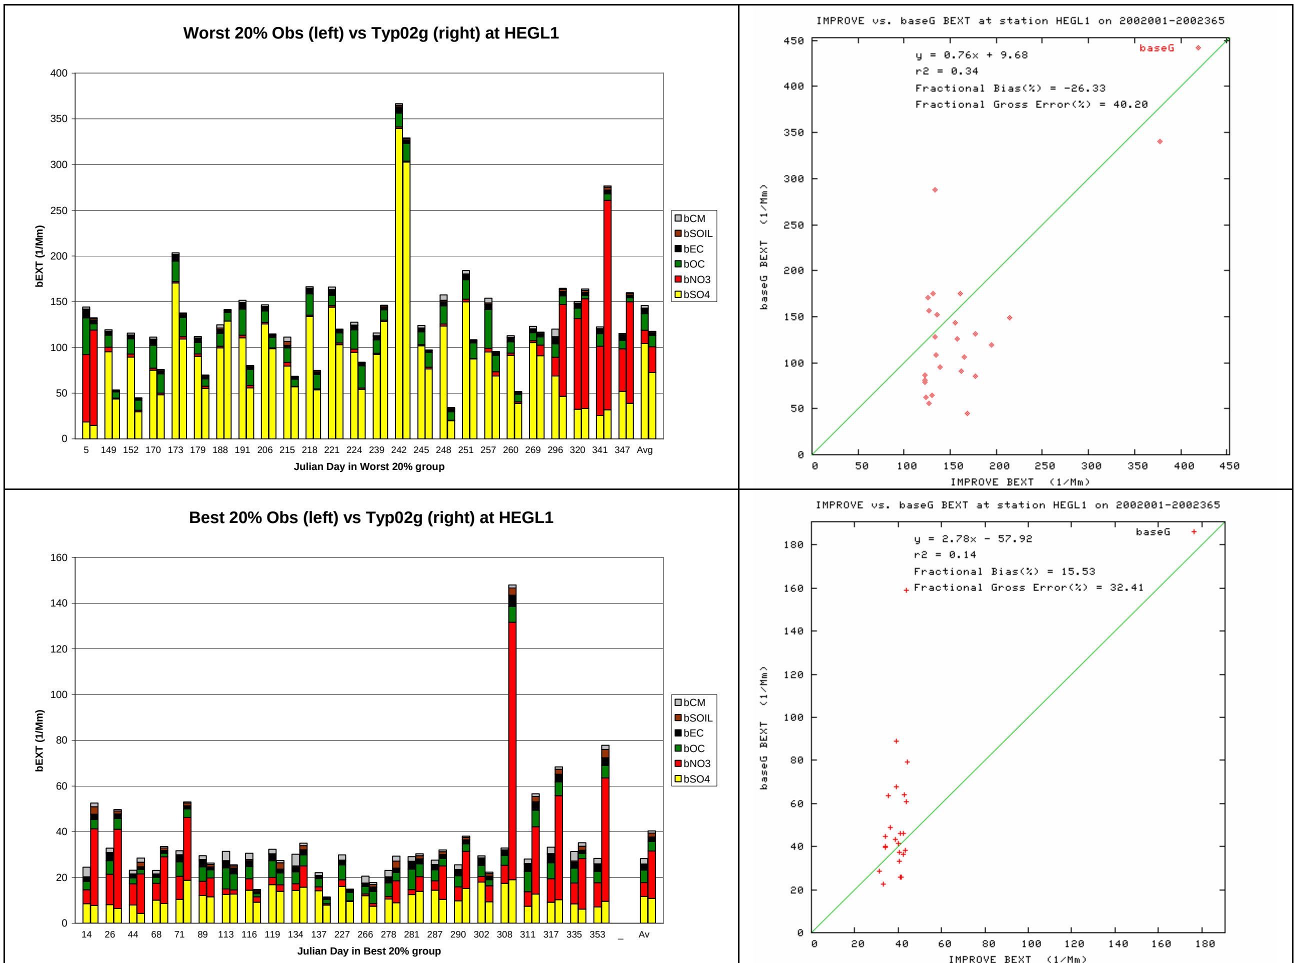

Figure 3-14. Daily extinction model performance at Hercules Glade (HEGL), Missouri for the worst (top) and best (bottom) 20 percent days during 2002.

3.7.7 Mingo (MING) Missouri

The worst 20 percent days at MING are mainly high SO4 days with a few high NO3 days that the model reproduces reasonably well resulting in low bias (+10%) and error (38%) for total extinction (Figure 3-15). The PM species specific performance is fairly good with low bias for SO4 (+4%), good agreement with NO3 on high NO3 days except for one day, low OMC (+23%) and EC (+3%) bias and larger bias in EC (+37%) and CM (-105%) extinction (Figure C-54).

For the best 20 percent days, there is one day the model is way too high due to overstated NO3 extinction and a few other days the model overstates the observed extinction that is usually due to overpredicted NO3, but on most of the best 20 percent days the modeled extinction is comparable to the observed values. This results in low bias (+12%) and error (36%) for total extinction at MING for the best 20 percent days.

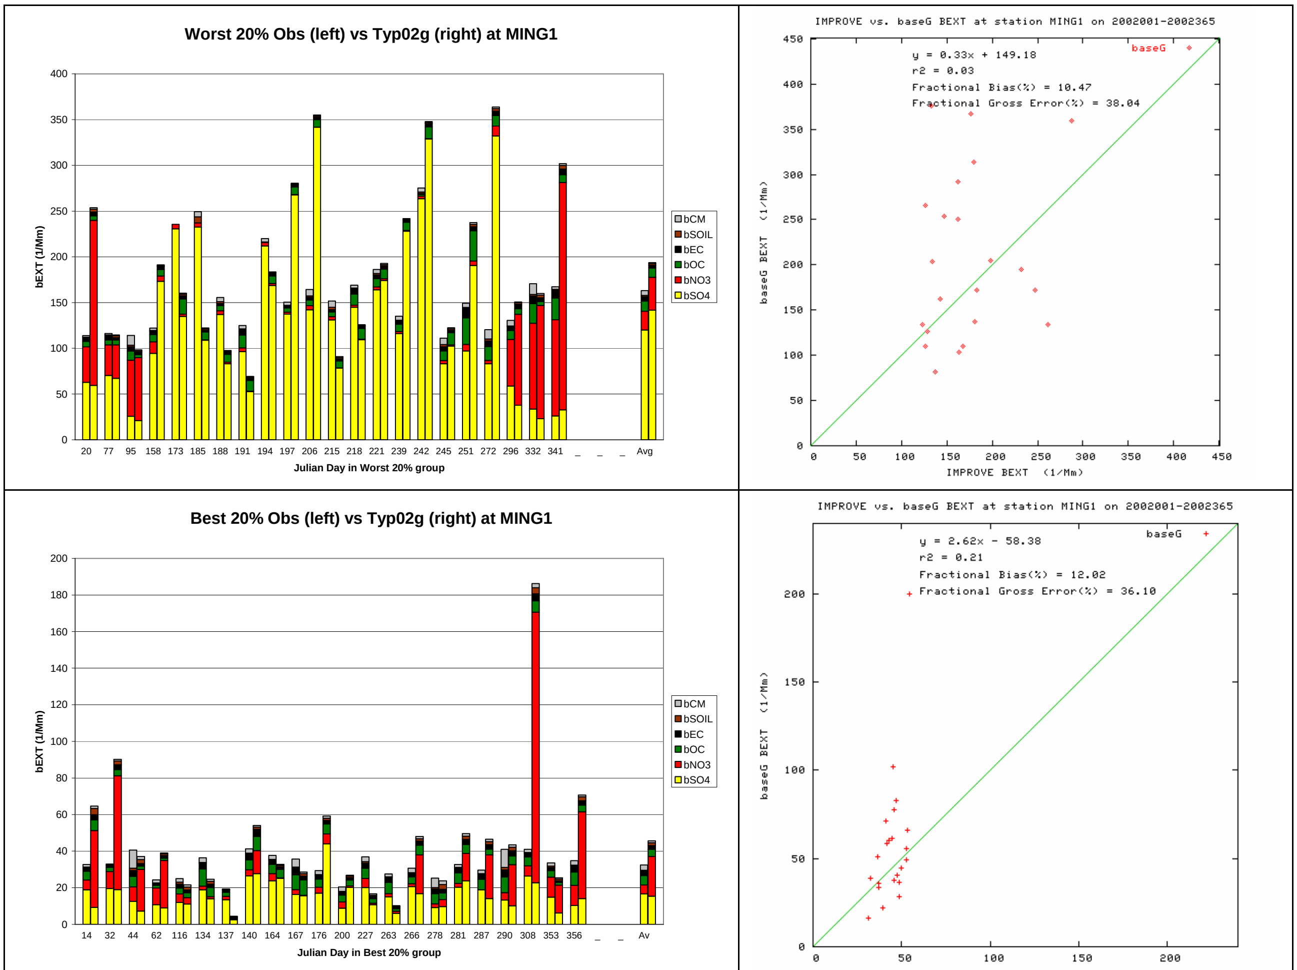

Figure 3-15. Daily extinction model performance at Mingo (MING), Missouri for the worst (top) and best (bottom) 20 percent days during 2002.

3.7.8 Wichita Mountains (WIMO), Oklahoma

With the exception of an overprediction on day 344 due to NO3, observed total extinction on the worst 20 percent days at WIMO is understated with a bias of -42% (Figure 3-16) that is primarily due to an underestimation of extinction due to SO4 (-48%) and OMC (-69%) (Figure C-55).

CMAQ total extinction performance for the average of the best 20 percent days at WIMO is characterized by an overestimation bias (+21%) on most days that is primarily due to NO3 overprediction on several days. Again the modeled range of extinction on the best 20 percent days (12-60 Mm^{-1}) is much greater than observed (20-35 Mm^{-1}).

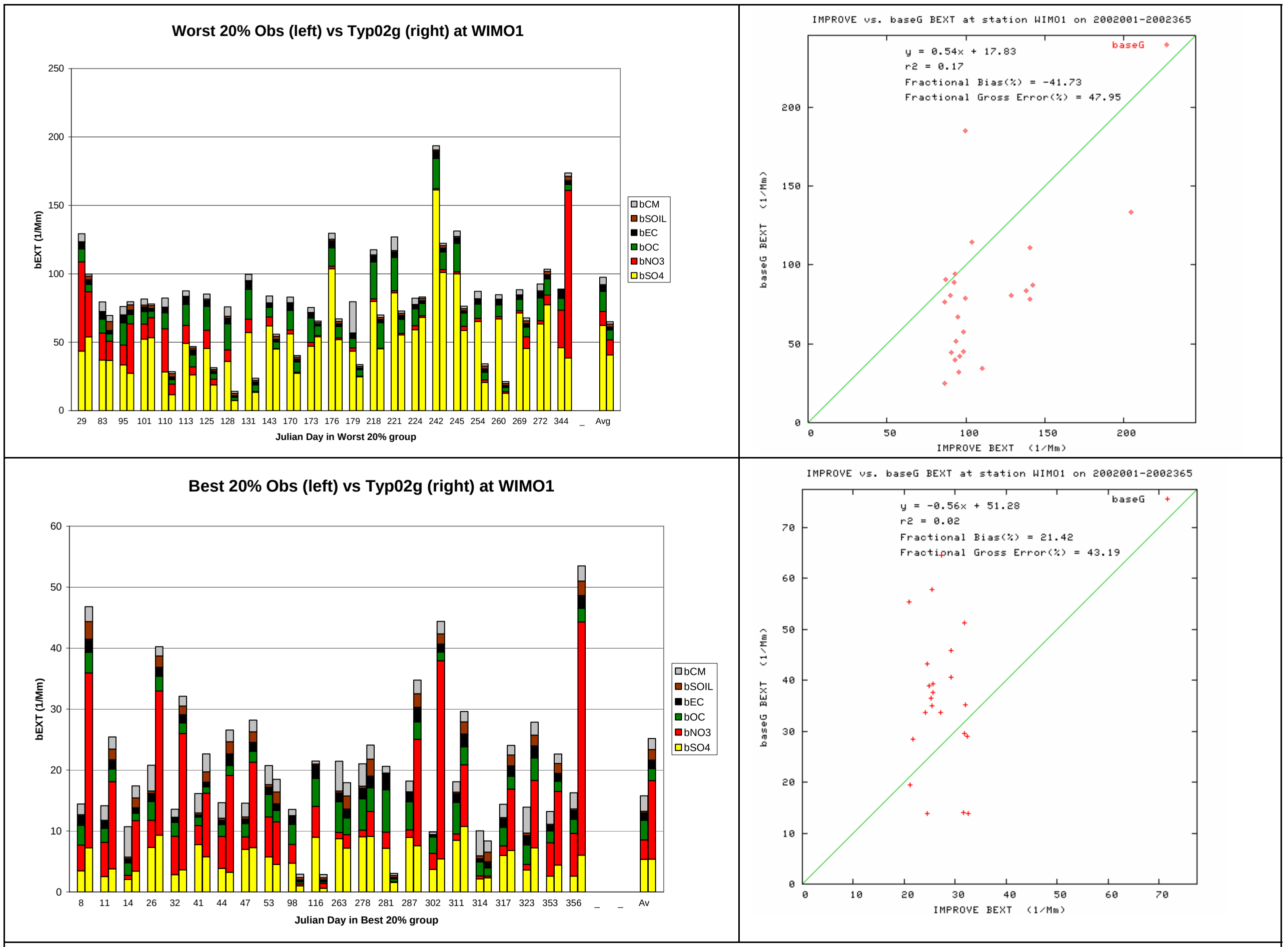

Figure 3-16. Daily extinction model performance at Wichita Mountains (WIMO), Oklahoma for the worst (top) and best (bottom) 20 percent days during 2002.

3.7.9 Big Bend (BIBE) Texas

The observed extinction on the worst 20 percent days at BIBE is underpredicted on almost every day resulting in a fractional bias value of -72% (Figure 3-17). Every component of extinction is underestimated on average for the worst 20 percent days (Figure C-56) with the underestimation bias ranging from -24% (OMC) to -162% (CM). SO4 extinction, that typically represents the largest component of the total extinction is understated by -94%.

The model does a better job in predicting the total extinction at BIBE for the best 20 percent days with average fractional bias and error values of +13% and 19% (Figure 3-17). With the exception of one day that the observed extinction is overestimated by approximately a factor of 2, the modeled and observed extinction on the best 20 percent days at BIBE are both within 12 to 25 Mm^{-1}. However, there are some mismatches with the components of extinction with the model estimating much lower contributions due to Soil and CM.

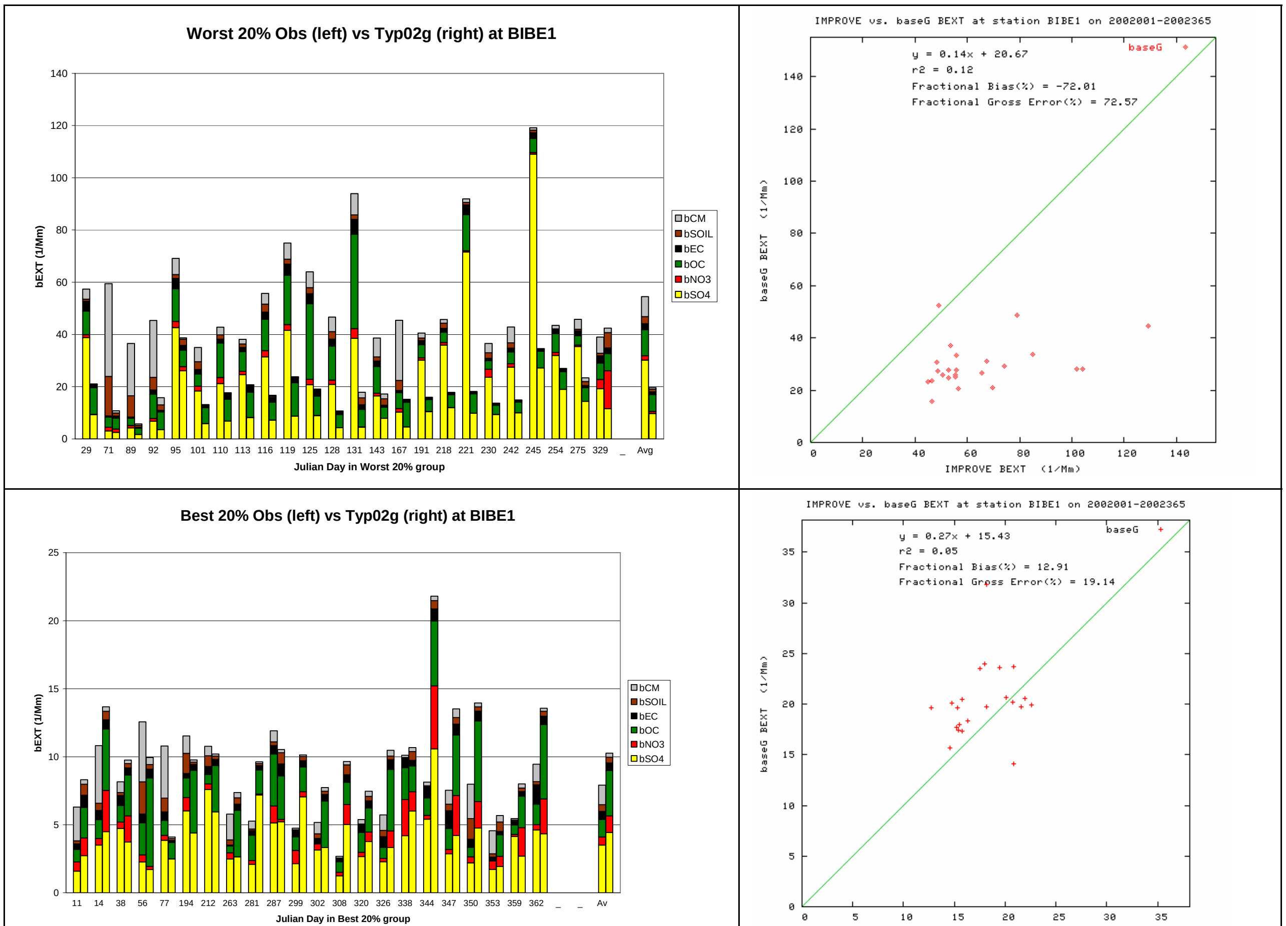

Figure 3-17. Daily extinction model performance at Big Bend (BIBE), Texas for the worst (top) and best (bottom) 20 percent days during 2002.

3.7.10 Guadalupe Mountains (GUMO) Texas

Most of the worst 20 percent days at GUMO are high dust days with high Soil and CM that is not captured by the model (Figure 3-18). Extinction due to Soil and CM on the worst 20 percent days is underestimated by -105% and -191%, respectively (Figure C-57). Better performance is seen on the best 20 percent days with bias and error for total extinction of 8% and 21%, but the model still understates Soil and CM.

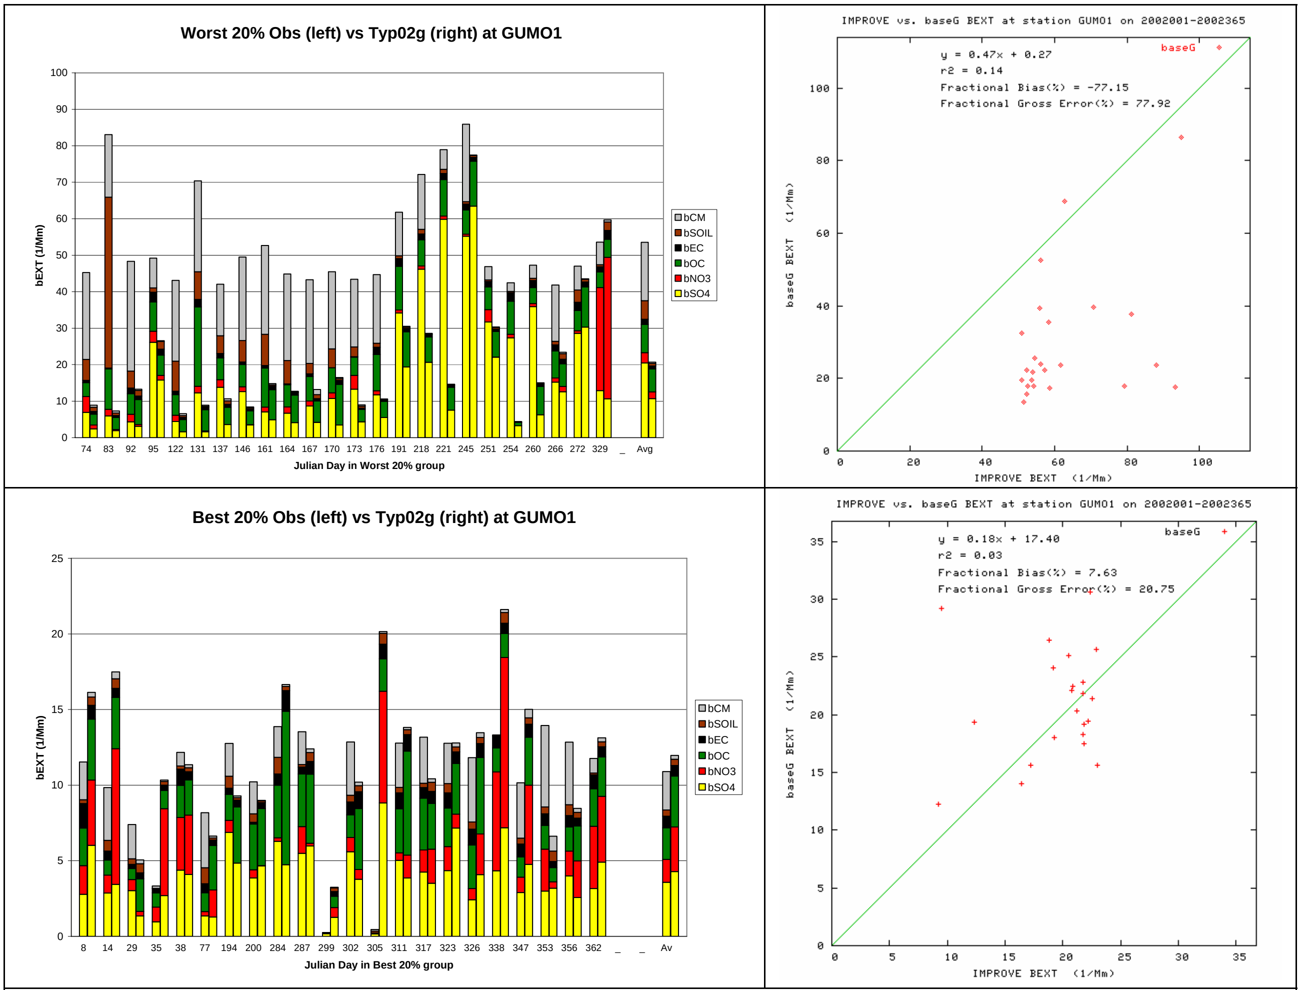

Figure 3-18. Daily extinction model performance at Guadalupe Mountains (GUMO), Texas for the worst (top) and best (bottom) 20 percent days during 2002.

3.8 Model Performance Evaluation Conclusions

The model performance evaluation reveals that the model is performing best for SO4, OMC and EC. Soil performance is mixed with a winter overestimation bias with lower bias and higher error in the summer. CM performance is poor year round. The operational evaluation reveals that SO4 performance usually achieves the PM model performance goal and always achieves the model performance criteria, although it does have an underestimation bias that is greatest in the summer. NO3 performance is characterized by a winter overestimation bias with an even greater summer underestimation bias. However, the summer underestimation bias occurs when NO3 is very low and when it is not an important component of the observed or predicted PM mass concentrations or component of visibility impairment. Performance for OMC meets the model performance goal year round at the IMPROVE sites, but is characterized by an underestimation bias at the more urban STN sites. EC exhibits very low bias at the STN sites and a summer underestimation bias at the IMPROVE sites, but meets the model performance goal throughout the year. Soil has a winter overestimation bias that is outside of the model performance goal and criteria raising questions whether the model should be used for this species. Finally, CM performance is extremely poor with an underprediction bias that is outside of the performance goal and criteria. We suspect that much of the CM concentrations measured at the IMPROVE sites is due to highly localized emissions from fugitive dust sources that are not included in the emissions inventory and would be difficult to simulate using 36 km regional modeling.

Performance for the worst 20 percent days at the CENRAP Class I areas is generally characterized by an underestimation bias. Performance at the BRET, BIBE and GUMO Class I areas for the worst 20 percent days is particularly suspect and care should be taken in the interpretation of the visibility projections at these three Class I areas.

The CMAQ 2002 36 km model appears to be working well enough to reliably make future-year projections for changes in SO4, NO3, EC and OMC at the rural Class I areas. Performance for Soil and especially CM is suspect enough that care should be taken in interpreting these modeling results. The model evaluation focused on the model's ability to predict the components of light extinction mainly at the Class I areas. Additional analysis would have to be undertaken to examine the model's ability to simulate ozone and fine particulate to address 8-hour ozone and $PM_{2.5}$ attainment issues.

4.0 VISIBILITY PROJECTIONS

This section presents the future-year visibility projections for Class I areas within and near the CENRAP states and their comparison with the 2018 Uniform Rate of Progress (URP) point. As noted in Chapter 1, the Regional Haze Rule (RHR) requires states with Class I areas to develop State Implementation Plans (SIPs) that include reasonable progress goals (RPGs) for improving visibility in each Class I area and emission reduction measures to meet those goals. For the initial SIPs due in December 2007, states are required to adopt RPGs for improving visibility from Baseline Conditions. The 2000-2004 five-year period is used to define Baseline Conditions and the first future progress period is 2018. A state is required to set RPGs for each Class I area in the state for two visibility metrics:

- Provide for an improvement in visibility for the most impaired visibility days (i.e., the worst 20 percent days); and

- Ensure no degradation in visibility for the least impaired visibility days (i.e., the best 20 percent days).

The goal of the RPGs is to provide for a rate of improvement sufficient to be on a course to attain "Natural Conditions" by 2064. States are to define controls to meet RPGs every 10 years, starting in 2018, which defines progress periods ending in 2018, 2028, 2038, 2048, 2058 and finally 2064. States will determine whether they are meeting their goals by comparing visibility conditions from one five-year period to another (e.g., 2000-2004 to 2013-2017). As stated in 40 CFR 51.308 (d) (1), baseline visibility conditions, reasonable progress goals, and changes in visibility must be expressed in terms of deciview (dv) units. The haze index (HI) metric of visibility impairment, in deciviews, is derived from light extinction (b_{ext}) as follows:

$$HI = 10 \ln (b_{ext}/10),$$

Where light extinction (b_{ext}) is expressed in terms of inverse megameters ($Mm^{-1} = 10^{-6}\ m^{-1}$). Light extinction ($b_{ext}$) is calculated using the observed fine particulate concentrations from the IMPROVE monitors using either the original or the new IMPROVE aerosol extinction equation. Both equations are discussed below.

4.1 Guidance for Visibility Projections

EPA has published several guidance documents that relate to how modeling results should be used to project future-year visibility and how states should define RPGs:

"Guidance on the Use of Models and Other Analyses for Demonstrating Attainment of Air Quality Goals for Ozone, $PM_{2.5}$ and Regional Haze" (EPA, 2007a).

"Guidance for Tracking Progress Under the Regional Haze Rule" (EPA, 2003a).

"Guidance for Estimating Natural Visibility Conditions Under the Regional Haze Rule" (EPA, 2003b).

"Guidance for Setting Reasonable Progress Goals Under the Regional Haze Program" (EPA, 2007b).

The first EPA modeling guidance document listed above (EPA, 2007) discusses the use of modeling results to project future-year visibility. The second EPA guidance document (EPA, 2003a) focuses on monitored visibility, how to define the visibility Baseline Conditions and how to track visibility goals. The third EPA guidance document discusses procedures for defining Natural Conditions for a Class I area. Natural Conditions are the visibility goal for 2064. Although states may propose alternative approaches for defining Natural Conditions, in this section we use the default Natural Conditions at Class I areas (EPA, 2003b; Pitchford, 2006). The final EPA guidance document discusses how states should define their RPGs and their relationship to the 2018 URP point.

The EPA documents discussed above are followed for the visibility projections presented in this section with one notable exception. Some of the EPA documents are based on the original IMPROVE equation (e.g., EPA, 2003a, b). The CENRAP visibility projections are based on the new IMPROVE equation, although projections based on the original IMPROVE equation are also presented as an alternative approach in Chapter 5. EPA guidance allows for using either the original or the new IMPROVE equation (EPA, 2007a; Timin, 2007). CENRAP, along with the other RPOs, have elected to use the new IMPROVE equation for their visibility projections.

4.2 Calculation of Visibility and 2018 URP Point from IMPROVE Measurements

EPA guidance recommends using the model in a relative sense to project future-year visibility conditions (EPA, 2007a). This projection is made using Relative Response Factors (RRFs) that are defined as the ratio of the future-year modeling results to the base-year modeling results. The RRFs are applied to the baseline visibility conditions to project future-year visibility. The major features of EPA's recommended visibility projection approach are as follows (EPA, 2003a,b; 2007a):

- Monitored data are used to define current visibility Baseline Conditions using IMPROVE monitoring data from the 2000-2004 five-year base period.

- Monitored concentrations of PM_{10} are divided into six major components, the first five of which are assumed to be $PM_{2.5}$ and the sixth is coarse mass (CM or $PM_{2.5-10}$).
  - SO4 (sulfate) that is assumed to be ammonium sulfate [$(NH_4)_2SO_4$];
  - NO3 (particulate nitrate) that is assumed to be ammonium nitrate [NH_4NO_3];
  - OC (organic carbon) that is assumed to be total organic mass carbon (OMC)
  - EC (elemental carbon);
  - IP (other fine inorganic particulate or Soil); and
  - CM (coarse mass).

- Models are used in a relative sense to develop RRFs between baseline and future predicted concentrations of each component.

- PM component-specific RRFs are multiplied by observed Baseline monitored values to estimate future-year PM component concentrations.
- Estimates of future-year component concentrations are consolidated to provide an estimate of future-year air quality and visibility using either the original or new IMPROVE equation.
- Future-year model projected visibility is compared with the 2018 point on the URP glidepath to assist in evaluating the visibility improvements.
- It is assumed that all measured sulfate is in the form of ammonium sulfate [$(NH_4)_2SO_4$] and all particulate nitrate is in the form of ammonium nitrate [NH_4NO_3].

In order to facilitate tracking visibility progress, three important visibility concepts are required for each Class I area:

<u>Baseline Conditions</u>: Baseline Conditions represent visibility for the 20 percent best (B20%) and 20 percent worst (W20%) visibility days for the initial five-year baseline period of the regional haze program. Baseline Conditions are calculated using IMPROVE monitor data collected during the 2000-2004 five-year period and are the starting point in 2004 for the URP glidepath and 2018 visibility projections.

<u>Natural Conditions</u>: Estimates of natural visibility conditions for the best 20 percent and worst 20 percent days at a Class I area (i.e., visibility conditions that would be experienced in the absence of human-caused impairment). EPA has defined a set of default Natural Conditions for the original IMPROVE equation (EPA, 2003b) that has been updated to the new IMPROVE equation by the Natural Haze Levels II Committee (Pitchford, 2006) that we have used in this Chapter.

<u>2018 URP Point</u>: The 2018 Uniform Rate of Progress (URP) point is defined by defining a linear glidepath in deciviews starting with the 2000-2004 Baseline Conditions in 2004 and ending at Natural Conditions in 2064. Where the linear glidepath passes through 2018 is the 2018 URP point in deciviews.

4.2.1 Calculation of Visibility from IMPROVE PM Measurements

Baseline Conditions for Class I areas are calculated using the procedures in EPA's guidance document (EPA, 2003a) and fine and coarse particulate matter concentrations measured at IMPROVE monitors (Malm et al, 2000; Debell et al., 2006). Currently, each Class I area in the CENRAP domain has an associated IMPROVE monitor. The IMPROVE monitors do not directly measure visibility, but instead measure speciated fine particulate ($PM_{2.5}$) and total $PM_{2.5}$ and PM_{10} mass concentrations from which visibility is obtained through the IMPROVE equation.

Visibility conditions are estimated starting with the IMPROVE 24-hour average mass measurements for six PM species:

- Sulfate [$(NH_4)_2SO_4$];
- Particulate Nitrate [(NH_4NO_3];
- Organic Matter Carbon or Organic Mass by Carbon [OMC];
- Elemental Carbon [EC] or Light Absorbing Carbon [LAC];
- Other fine particulate [Soil]; and
- Coarse Matter or Coarse Mass [CM].

The IMPROVE monitors do not directly measure some of these species so assumptions are made as to how the IMPROVE measurements can be adjusted and combined to obtain these six components of light extinction. For example, in the IMPROVE equation sulfate and particulate nitrate are assumed to be completely neutralized by ammonium. In addition, only the fine mode ($PM_{2.5}$) of PM is speciated by the IMPROVE monitor to obtain sulfate and nitrate measurements (that is, any coarse mode sulfate and nitrate in the real atmosphere may be present in the CM IMPROVE measurement). Concentrations for the above six components of light extinction in the IMPROVE equation are obtained from the IMPROVE measured species using the mappings shown in Table 4-1:

Table 4-1. Definition of IMPROVE PM Components from Measured IMPROVE Species.

IMPROVE Component	IMPROVE Measured Species
Sulfate	1.375 x (3 x S)
Nitrate	1.29 x NO_3^-
OMC	1.4*OC (original IMPROVE) and 1.8*OC (new IMPROVE)
LAC	EC
Soil	2.2*AL + 2.49*SI + 1.63*CA + 2.42*FE + 1.94*TI
CM	MT – MF

Where:

- S is elemental sulfur as determined from proton induced x-ray emissions (PIXE) analysis of the IMPROVE Module A[1]. To estimate the mass of the sulfate ion ($SO_4^{=}$), S is multiplied by 3 to account the presence of oxygen. If S is missing then the sulfate (SO_4) measured by ion chromatography analysis of the Module B is used to replace (3 x S). For the IMPROVE aerosol extinction calculation, Sulfate is assumed to be completely neutralized by ammonium (1.375 x SO_4).
- NO_3^- is the particulate nitrate measured by ion chromatography analysis of the Module B. For the IMPROVE aerosol extinction calculation, it is assumed to be completely neutralized by ammonium (1.29 x NO_3^-).
- The IMPROVE Organic Carbon (OC) measurements are multiplied by 1.4 to obtain Organic Mass Carbon (OMC) using the original IMPROVE equation and multiplied by 1.8 for the new IMPROVE equation. This adjustment of the measured OC accounts for mass due to other elements in the OMC besides Carbon.
- Elemental Carbon (EC) is also referred to as Light Absorbing Carbon (LAC).

[1] The IMPROVE sampler consists of four independent modules (A, B, C and D). Each module incorporates a separate inlet, filter pack and pump assembly and are controlled by a common timing mechanism. Module A measures fine PM mass and elements. Module B measures sulfate and nitrate ions. Module C measures EC and OC. Module D measures PM_{10} mass. (see http://vista.cira.colostate.edu/improve/ for more details).

- Soil is determined as a sum of the masses of those elements (measured by PIXE) predominantly associated with soil (Al, Si, Ca, Fe, K and Ti), adjusted to account for oxygen associated with the common oxide forms. Since K and FE are products of the combustion of vegetation, they are both represented in the formula by 0.6 x Fe and K is not shown explicitly.
- MT and MF are total PM_{10} and $PM_{2.5}$ mass, respectively.

4.2.1.1 Original and New IMPROVE Equations

Associated with each PM species is an extinction efficiency that converts concentrations (in $\mu g/m^3$) to light extinction (in inverse megameters, Mm^{-1}). Sulfate and nitrate are hygroscopic which means that they can absorb water from the atmosphere which changes their extinction efficiency. This is accounted for through relative humidity adjustment factors [f(RH)] that increase the particle's extinction efficiency with increasing RH to account for the particles taking on water Note that some OMC may also have hygroscopic properties, but the IMPROVE equations assume OMC is non-hygroscopic.

There are currently two IMPROVE equations that are used to convert the measured PM concentrations to light extinction, the original (or old) and the new IMPROVE equations.

4.2.1.1.1 Original IMPROVE Equation

The original IMPROVE equation that converts PM species concentrations to light extinction is given as follows:

$$
\begin{aligned}
b_{Sulfate} &= 3 \times f(RH) \times [Sulfate] \\
b_{Nitrate} &= 3 \times f(RH) \times [Nitrate] \\
b_{EC} &= 10 \times [EC] \\
b_{OMC} &= 4 \times [OMC] \\
b_{Soil} &= 1 \times [Soil] \\
b_{CM} &= 0.6 \times [CM]
\end{aligned}
$$

Monthly average f(RH) factors are used as recommended in EPA's guidance (EPA, 2003a). These values are available in the final EPA guidance document (EPA, 2003a) and at: ftp://ftp.saic.com/raleigh/RegionalHaze_2002FRHcurve/fRH_analysis/.

The total light extinction (b_{ext}) is assumed to be the sum of the light extinction due to the six PM species listed above plus Rayleigh (blue sky) background (b_{Ray}) that is assumed to be 10 Mm^{-1}.

$$b_{ext} = b_{Ray} + b_{Sulfate} + b_{Nitrate} + b_{EC} + b_{OMC} + b_{Soil} + b_{CM}$$

The total light extinction (b_{ext}) in Mm^{-1} is related to visual range (VR) in km using the following relationship:

$$VR = 3912 / b_{ext},$$

for b_{ext} in Mm^{-1}.

The Regional Haze Rule requires that visibility be expressed in terms of a haze index (HI) in units of deciviews (dv), which is calculated as follows:

$$HI = 10 \ln(b_{ext}/10)$$

4.2.1.1.2 New IMPROVE Equation

The new IMPROVE equation is nonlinear in SO4, NO3 and OMC concentrations accounting for the different light scattering efficiency characteristics as a function of concentrations for these three species. It is expressed as follows:

$$b_{Sulfate} = 2.2 \times f_S(RH) \times [\text{Small Sulfate}] + 4.8\ f_S(RH) \times [\text{Large Sulfate}]$$
$$b_{Nitrate} = 2.4 \times f_S(RH) \times [\text{Small Nitrate}] + 5.1\ f_S(RH) \times [\text{Large Nitrate}]$$
$$b_{EC} = 10 \times [\text{Elemental Carbon}]$$
$$b_{OMC} = 2.8 \times [\text{Small Organic Mass}] + 6.1 \times [\text{Large Organic Mass}]$$
$$b_{Soil} = 1 \times [\text{Fine Soil}]$$
$$b_{CM} = 0.6 \times [\text{Coarse Mass}]$$
$$b_{NaCl} = 1.7 \times f_{SS}(RH) \times [\text{Sea Salt}]$$
$$b_{NO2} = 0.33 \times [NO_2\ (\text{ppb})]$$

The total Sulfate, Nitrate and OMC are each split into two fractions, representing small and large size distributions of those components. As noted in Table 4-1, the OMC is 1.8 times the IMPROVE OC measurement in the new IMPROVE algorithm, compared to 1.4 times the IMPROVE OC measurement in the original IMPROVE equation. New terms have been added for Sea Salt (important for coastal areas and possibly other areas)and for light absorption by NO2 (only used where NO2 observations are available). As none of the CENRAP Class I area IMPROVE sites measure NO2 concentrations, then this component of the new IMPROVE equations was not used. Site-specific Rayleigh scattering for each IMPROVE monitoring site is used in the new IMPROVE equation, as compared to a constant 10 Mm^{-1} value assumed in the original IMPROVE equation.

The apportionment of the Small and Large components of Sulfate, Nitrate and Organic Mass is done as follows:

$$[\text{Large Sulfate}] = [\text{Total Sulfate}] / 20 \times [\text{Total Sulfate}], \text{ for } [\text{Total Sulfate}] < 20\ \mu g/m^3$$

$$[\text{Large Sulfate}] = [\text{Total Sulfate}], \text{ for } [\text{Total Sulfate}] \geq 20\ \mu g/m^3$$

$$[\text{Small Sulfate}] = [\text{Total Sulfate}] - [\text{Large Sulfate}]$$

The same equations are used to apportion Total Nitrate and Total OMC among their Large and Small components.

The total extinction (b_{ext}) in the new IMPROVE equations is the sum of all the extinction components associated with each PM species. The new IMPROVE equation adds Sea Salt and

NO_2 as noted above. In addition, site-specific Rayleigh background is used with the new IMPROVE equation:

$$b_{ext} = b_{Ray} + b_{Sulfate} + b_{Nitrate} + b_{EC} + b_{OMC} + b_{Soil} + b_{CM} + b_{NaCl} + b_{NO2}$$

The Haze Index (HI) and Visual Range (VR) are calculated from the total extinction from the new IMPROVE equation using the same formulas as given above for the original IMPROVE equation.

4.2.1.1.3 Justification for Using the New IMPROVE Equation

The new IMPROVE equation was developed using the latest scientific information on PM species extinction properties combined with fitting reconstructed light extinction based on IMPROVE measured PM and NO2 concentrations with actual co-located measured light extinction (e.g., nephelometer measurements). Figure 4-1 displays example comparisons of 24-hour light extinction using the original and new IMPROVE equations compared against 24-hour nephelometer measurements of light extinction at the Great Smoky Mountains Class I area IMPROVE monitor. The original IMPROVE equation has a bias toward understating light extinction at the high end and overstating it at the low end, whereas the new IMPROVE equation does a better job in estimating light extinction from measured PM at all extinction levels. Because the new IMPROVE equation is based on more recent science and fits the observed light extinction values better, the CENRAP states have elected to perform their primary visibility projections using the new IMPROVE equation. Results using the original IMPROVE equation are presented in Section 5 as an alternative approach.

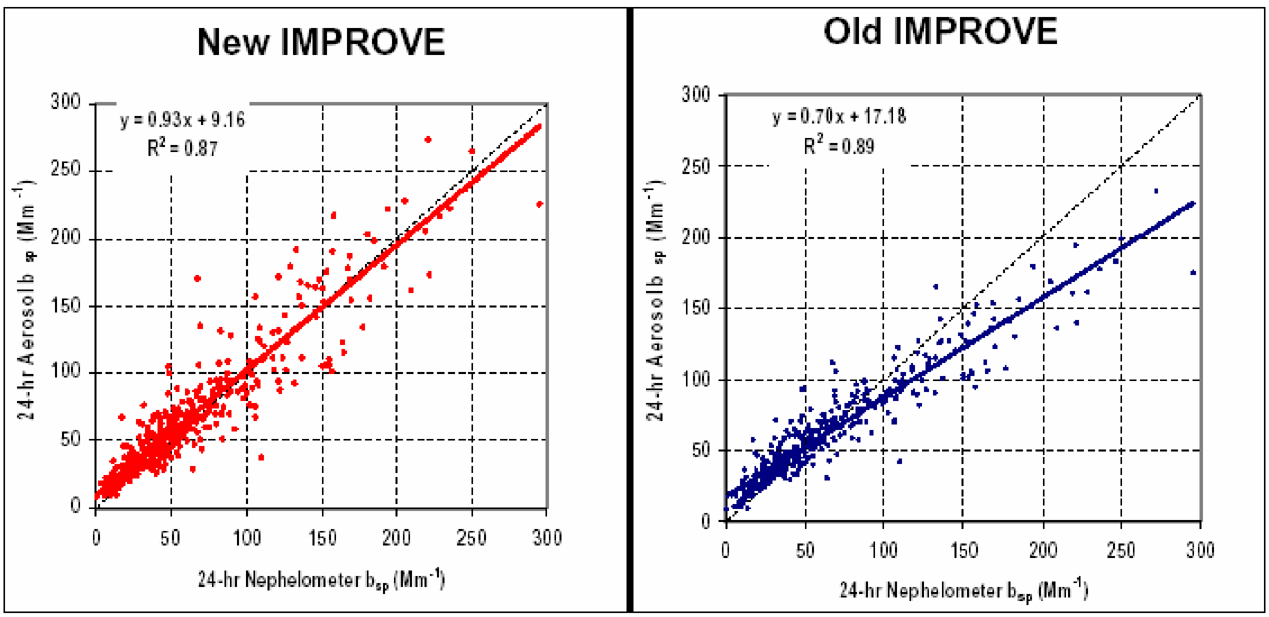

Figure 4-1. Comparisons of observed light extinction with reconstructed light extinction using the new (left) and original (right) IMPROVE equations at the Great Smoky Mountains National Park.

4.2.2 Calculation of the Baseline Conditions

The visibility Baseline Conditions for the worst 20 percent and best 20 percent days is calculated from the IMPROVE observations from the 2000-2004 period for each Class I area following EPA's guidance (EPA, 2003a). The basic procedures for calculating the Baseline Conditions are as follows:

1. Determine whether the observed IMPROVE data for each site and year satisfies EPA's minimal data capture criteria (EPA, 2003a). If there are less than three years with valid data capture for the 2000-2004 Baseline then the Baseline Conditions can not be calculated and data filling is needed.
2. For each year in the 2000-2004 period with sufficient valid data, rank the visibility in terms of extinction or deciview using either the original or new IMPROVE equation and monthly average f(RH) factors (EPA, 2003a).
3. For the worst 20 percent days, extract the 20% most impaired visibility days for each year (similarly for best 20 percent days extract 20% cleanest days). With a complete yearly data capture of IMPROVE 1:3 day sampling frequency this would result in 24 worst 20 percent and 24 best 20 percent days in a year.
4. For each worst 20 percent (or best 20 percent) day in each year, calculate 24-hour average visibility extinction using the IMPROVE measurements and either the original and new IMPROVE equation, convert the daily extinction to daily deciview and then average across each year to get yearly average deciview extinction for the worst 20 percent (or best 20 percent) days for each valid year from the 2000-2004 period.
5. Average the annual average deciview worst 20 percent (or best 20 percent) days deciview across each valid year in the 2000-2004 period (minimum of 3 valid years required) to get the worst 20 percent (or best 20 percent) Baseline Conditions.

4.2.3 Data Filling for Sites with Insufficient Valid Data to Calculate Baseline Conditions

Three CENRAP Class I areas did not contain sufficient IMPROVE observations during the five-year 2000-2004 Baseline to have three valid years of data from which Baseline Conditions could be constructed: Breton Island (BRET), Louisiana; Boundary Waters (BOWA), Minnesota and Mingo (MING), Missouri. For these three Class I areas, data filling was used to obtain sufficient data so that at least three-years of valid data were available from which Baseline Conditions could be calculated. These data filled IMPROVE databases were prepared and made available on the VIEWS website. More information on the data filling procedures can be found at the VIEWS website: (http://vista.cira.colostate.edu/views/).

4.2.4 Natural Conditions

EPA has published default Natural Conditions for Annual Average and the worst 20 percent and best 20 percent days based on the original IMPROVE equation (EPA, 2003b). These default Natural Conditions have been updated to the new IMPROVE equation by the Natural Haze Levels II Committee (Pitchford, 2006). These default Natural Conditions are used as the anchor point for the glidepaths in 2064 and are provided in Appendix D for the CENRAP Class I areas.

4.2.5 2018 URP Point

The 2018 point on the Uniform Rate of Progress (URP) glidepath is constructed by generating a linear glidepath in deciviews from the Baseline Conditions in 2004 to Natural Conditions in 2064. Where the linear glidepath crosses 2018 is the 2018 point on the URP glidepath or the 2018 URP point. Figure 4-2 displays an example linear glidepath for the Caney Creek Class I area in Arkansas. There are three years of sufficient valid IMPROVE data during the 2000-2004 Baseline (2002, 2003 and 2004) with values of 27.21, 26.52 and 25.34 dv resulting in worst 20 percent Baseline Conditions of 26.36 dv that is placed as the starting point in 2004 for the glidepath. The ending point for the glidepath is 11.58 dv which is the default Natural Conditions for the worst 20 percent days (EPA, 2003b; Pitchford, 2006). The linear glidepath crosses 2018 at 22.91 dv which becomes the 2018 URP point.

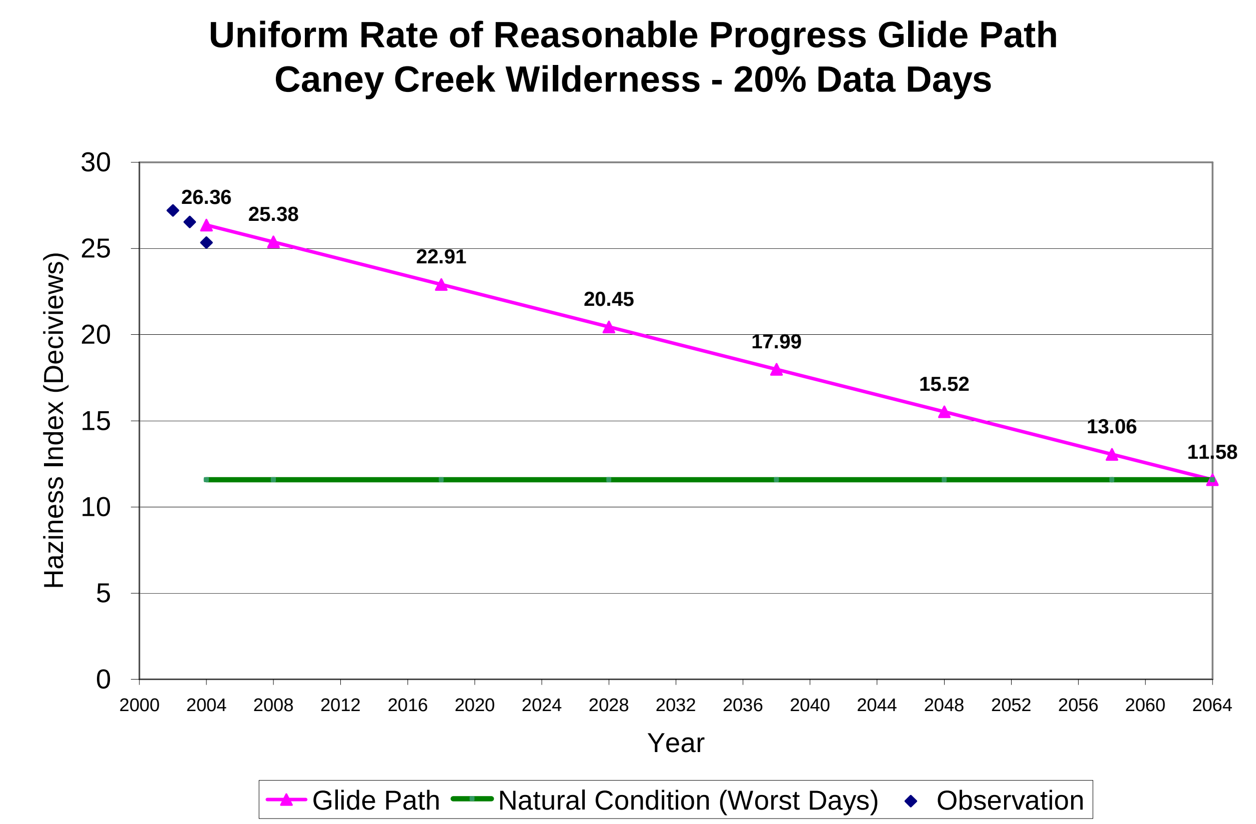

Figure 4-2. Linear Glidepath for Caney Creek (CACR), Arkansas that linearly connects the 26.36 dv Baseline Conditions in 2004 with the 11.58 dv Natural Conditions in 2064 resulting in a 22.91 dv 2018 URP Point.

4.3 EPA Default Approach to Visibility Projections

For CENRAP's model application for a single year (2002), EPA's regional haze modeling guidance recommends developing Class I area-specific and PM species-specific RRFs based on the average concentrations for the worst 20 percent days from 2002 (EPA, 2007). Thus, this is

the methodology used to project 2018 visibility estimates in this section. For example, if $SO4(2002)_i$ and $SO4(2018)_i$ are the model estimated sulfate concentrations for the 2002 worst 20 percent days (i=1…N) at a given Class I area for the 2002 and 2018 emission scenarios then the RRF for sulfate and this Class I area is given by:

$$RRF(SO4)_i \quad = \quad \sum SO4(2018)_i \,/\, \sum SO4(2002)_i$$

4.3.1 Mapping of Modeling Results to the IMPROVE Measurements

As noted above, to project future-year visibility at Class I areas the modeling results are used in a relative sense to scale current observed visibility for the worst 20 percent and best 20 percent visibility days using RRFs that are the ratio of modeling results for the future-year to current-year. This scaling is done separately for each of the six components of light extinction in the IMPROVE equations. The CMAQ modeled species do not necessarily exactly match up with the IMPROVE PM species, thus assumptions must be made to map the modeled species to the IMPROVE PM species for the purpose of projecting visibility improvements. For example, CMAQ explicitly simulates ammonium and sulfate may or may not be fully neutralized in the model by ammonium, whereas the IMPROVE equations assume sulfate is fully neutralized by ammonium. For the CMAQ Version 4.5 (September 15, 2005 release) model, the mapping of modeled species to IMPROVE equation PM species is listed in Table 4-2.

Table 4-2. Mapping of CMAQ V4.5 modeled species concentrations to IMPROVE PM components.

IMPROVE Component	CMAQ V4.3 Species
Sulfate	1.375 x (ASO4J + ASO4I)
Nitrate	1.29 x (ANO3J + ANO3I)
LAC	AECJ + AECI
OMC	AORGAJ + AORGAI + AORGPAJ + AORGPAI + AORGBJ + AORGBI
Soil	A25J + A25I
CM	ACORS + ASEAS + ASOIL

For the CENRAP visibility projections using the 2002 Typical and 2018 base case Base G emission scenarios, the secondary organic aerosol (SOA) module in CMAQ V4.5 was modified (SOAmods) to include additional processes related to the generation of SOA from biogenic emissions. In particular, three new species have been added that represent SOA products from biogenic emission compounds that is not included in the standard version of CMAQ V4.5 (Morris et al., 2006c):

- ASOC1 – SOA from biogenic sources (e.g., terpenes and isoprene) that has become polymerized so is no longer volatile.

- ASOC2 – SOA from biogenic sesquiterpene and higher reactivity and higher yield monoterpene emissions.

- ASOC3 – SOA from biogenic isoprene emissions.

Thus, the species mapping for Organic Mass Carbon (OMC) and the CMAQ V4.5 SOAmods version of the model used in CENRAP 2018 visibility projections is as given in Table 4-2 only with the addition of the three new biogenic SOA species to OMC as follows:

> OMC = AORGAJ + AORGAI + AORGPAJ + AORGPAI + AORGBJ + AORGBI + ASOC1 + ASOC2 + ASOC3

4.3.2 Using Modeling Results to Project Changes in Visibility

Modeling results are used in a relative fashion to project future-year visibility using relative response factors (RRFs). RRFs are expressed as the ratio of the modeling results for the future-year to the results of the base year (2018/2002) and are Class I area and PM species specific. RRFs are applied to the Baseline Condition observed PM species to project future-year PM levels from which visibility can be assessed using the IMPROVE equations listed above. The following six steps are used to project future-year visibility for the worst 20 percent and best 20 percent visibility days (discussion is for worst 20 percent days but also applies to best 20 percent days):

1. For each Class I area and each monitored day, daily visibility is ranked using IMPROVE data and IMPROVE equation (either original or new IMPROVE equation) for each year from the five-year baseline period (2000-2004) to identify the worst 20 percent visibility days for each year from the five-year baseline (see Baseline Conditions discussion above).

2. Use an air quality model to simulate a base year period (ideally the five-year Baseline period of 2000-2004, but for CENRAP just the 2002 annual period was simulated) and a future-year (e.g., 2018) and use the resulting information to develop Class I area-specific RRFs for each of the six components of light extinction in the IMPROVE equation (SO4, NO3, EC, OMC, Soil and CM).

3. Multiply the RRF times the measured 24-hour PM concentration data for each day from the worst 20 percent days in each year from the five-year Baseline period to obtain projected future-year 24-hour PM concentrations for the worst 20 percent days and the five-year Baseline.

4. Compute the future-year daily extinction using the IMPROVE equation and the projected PM concentrations for each of the worst 20 percent days in the five-year baseline from Step 3.

5. For each of the worst 20 percent days within each year of the five-year baseline, convert the future-year daily extinction to deciview and average the daily deciview values within each of the five years separately to obtain five-years (or as many years with valid data in the 2000-2004 Baseline) of average deciview visibility for the worst 20 percent days.

6. Average the five-years of average deciview visibility to obtain the future-year visibility Haze Index estimate that is the future-year estimated visibility.

In calculating the RRFs, EPA draft guidance recommends selecting estimated PM species concentrations "near" the monitor by taking a spatial average of PM concentrations across a grid cell resolution dependent NX by NY array of cells centered on the grid containing the monitor. The NX x NY array of cells is grid resolution specific with EPA recommending that NX=NY=1 for 36 km grids, NX=NY=3 for 12 km grids and NX=NY=7 for 4 km grids (EPA, 2007). For the CENRAP 2002 36 km modeling, just the model estimates for the grid cell containing the monitor was used (i.e., NX=NY=1).

4.4 EPA Default 2018 Visibility at CENRAP and Nearby Class I areas and Comparisons to 2018 URP Goals

Using the EPA default visibility projection procedure described in Section 4.3 and the CENRAP 2002 Typical Base G and 2018 Base Case Base G CMAQ modeling results, 2018 visibility projections were made for CENRAP and nearby Class I areas. Appendix D details the 2018 Base G visibility projections for each Class I area in the CENRAP region using the new IMPROVE equation. Results for the Caney Creek (CACR), Arkansas Class I area are discussed in Section 4.4.1 below Displays for other CENRAP Class I areas are provided in Appendix D and summarized in Section 4.4.2

4.4.1 Example 2018 Base G Visibility Projections for Caney Creek, Arkansas

The 2018 visibility projections for the Caney Creek (CACR), Arkansas Class I area given in Figure D-1 in Appendix D are reproduced in Figure 4-3 and described below.

4.4.1.1 EPA Default 2018 Visibility Projections

The 2018 Base G visibility projection using the EPA default method (EPA, 2007a) and comparison with the 2018 URP point for the worst 20 percent days and the CACR Class I area is shown in Figure 4-3a. The 2000-2004 Baseline Conditions for CACR is 26.36 dv and the 2018 URP point is 22.91 dv so that a 3.45 dv reduction in visibility for the worst 20 percent days is needed to meet the 2018 URP point. The 2018 Base G CMAQ projected visibility is 22.48 dv so that the modeling predicts more visibility improvements (3.88 dv reduction) than required to meet the 2018 URP point (3.45 dv reduction). When looking at visibility projections across several Class I areas, it has been useful to present the 2018 visibility projections as a percentage of meeting the 2018 URP point; where 100% is meeting the point, greater than 100% surpassing the point (i.e., below the glidepath) and less than 100% means that less visibility improvement is achieved than needed to meet the 2018 URP point. For 2018 Base G CMAQ modeling at CACR, we achieve 112% of the visibility reduction needed to meet the 2018 URP point. Note that meeting the 2018 URP point is not a requirement of the RHR SIPs, rather it just serves as a benchmark to compare progress toward Natural Conditions in 2064 and is designed to help states in selecting their 2018 RPGs. As clearly stated in EPA guidance "The glidepath is not a presumptive target, and States may establish a RPG that provides for greater, lesser, or equivalent improvement as that described by the glidepath" (EPA, 2007b).

The 2018 Base G CMAQ visibility projections for the best 20 percent days and CACR is shown in Figure 4-3b. Recall the RHR goal for this visibility metric is no worsening of the visibility for the best 20 percent days. The Baseline Conditions for the best 20 percent days at CACR is 11.24 dv. The 2018 Base G projected visibility for the best 20 percent days is 10.35 dv, which represents a 0.89 dv visibility improvement for the best 20 percent days at CACR and demonstrating no worsening in visibility for the best 20 percent days.

Figure 4-3c displays "StackedBar Chart" plots of observed and model estimated extinction for each of the worst 20 percent days in 2002 and the 2002 Typical Base G CMAQ simulation and the average across the worst 20 percent days. This figure allows a comparison of how well the model is reproducing the observed extinction at CACR for the worst 20 percent days in 2002 and the breakdown of the PM components that are contributing to visibility impairment (more details on model performance were presented in Chapter 3). The 2002 worst 20 percent days at CACR are dominated by SO4 days (yellow), although during the winter there are also three days dominated by NO3 (Julian Days 80, 320 and 341). For most of the worst 20 percent days at CACR, the model reproduces the observed extinction reasonably well, although it does tend to understate SO4 on a few days and overstate NO3 on the four winter days. The observed average extinction across the 2002 worst 20 percent days at CACR is 150 Mm^{-1}, compared to a modeled value that is 23% lower (115 Mm^{-1}).

Figure 4-3d displays "Boxplots" of differences in modeled extinction for the 2002 worst 20 percent days between the 2018 Base G and 2002 Typical Base G CMAQ simulations. On most days SO4 is the largest component of the extinction that is estimated to be reduced at CACR on the worst 20 percent days. The exception to this is for the winter NO3 days where NO3 is the largest component of extinction that is reduced. The modeling results are not used directly in the visibility projections, rather they are used to develop the PM-species specific RRFs. That is, an important attribute in Figures 4-3c and 4-3d is the relative changes in the modeled PM species averaged across the worst 20 percent days that are represented by the last bar in each figure and provide insight into the RRFs used in the visibility projections. These results are summarized in Table 4-3 below. Table 4-3 compares the average extinction across the 2002 worst 20 percent days at CACR from the measured IMPROVE data, the modeled values and the modeled change in extinction between the 2018 and 2002 emissions scenarios. Although the results in Table 4-3 are not RRFs (RRFs are based on ratios of concentrations not extinction) they do show how the RRFs may magnify or deflate the importance of a modeled PM species. For example, the model estimates that approximately 23% (26.66 Mm^{-1}) of the visibility extinction average across the worst 20 percent days is due to NO3, whereas it is only 7% in the observed values (10.22 Mm^{-1}). So the modeled ~40% reduction in NO3 between the 2018 and 2002 scenarios is applied to the smaller observed NO3 value to obtain the 2018 projected NO3 value making NO3 a smaller portion of the 2018 projected visibility than the 2018 modeled visibility. On the other hand, the modeled SO4 extinction is less than observed so that its importance in the 2018 projections is much greater than in the modeled 2018 SO4 values.

Table 4-3. Observed and Modeled Extinction by Species Averaged Across the Worst 20 Percent Days in 2002 at CACR.

	2002 Average Observed W20% (Mm^{-1})	2002 Average Modeled W20% (Mm^{-1})	2018-2002 Reduction (Mm^{-1})	2018-2002 Reduction (%)
bSO4	109.50	67.90	-24.47	-36%
bNO3	10.22	26.66	-10.90	-41%
bOMC	19.65	16.68	-2.12	-13%
bEC	4.38	2.32	-0.67	-29%
bSOIL	1.43	1.04	+0.21	+20%
bCM	4.30	0.37	-0.01	-3%

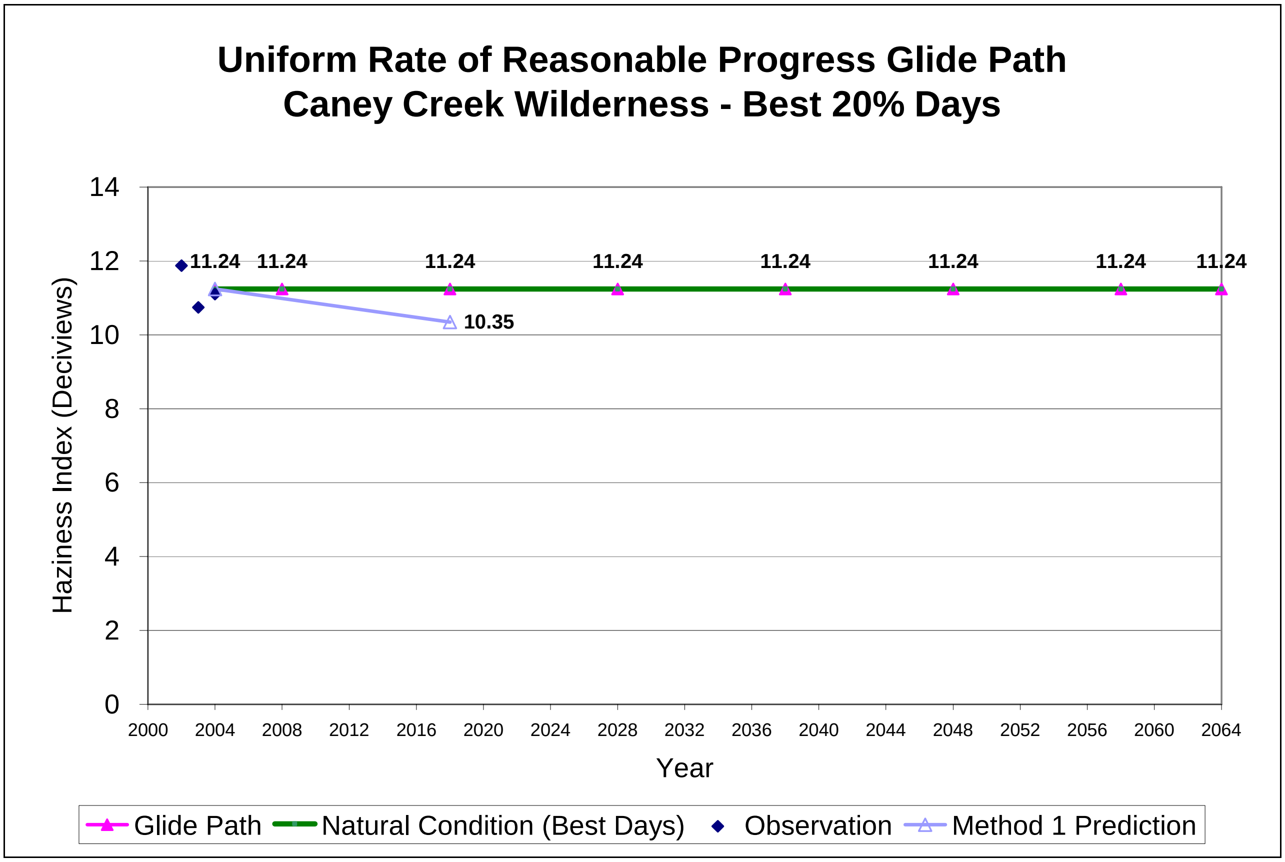

Figure 4-3b. 2018 Visibility Projections and 2018 URP Glidepaths in Deciview for CACR, Arkansas and Best 20 Percent (B20%) days Using 2002/2018 Base G CMAQ 36 m Modeling Results.

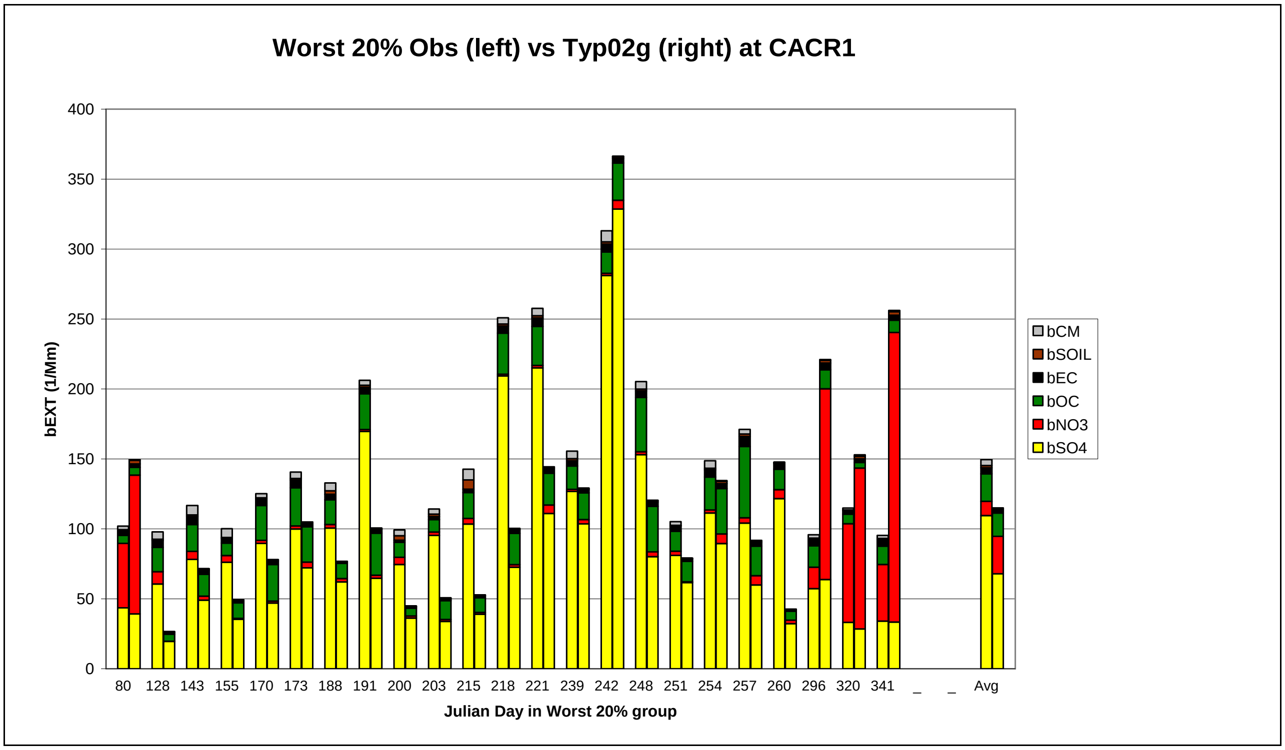

Figure 4-3c. Comparison of Observed (left) and 2002 Base G Modeled (right) Daily Extinction for Caney Creek (CACR), Arkansas and Worst 20 Percent (W20%) days in 2002.

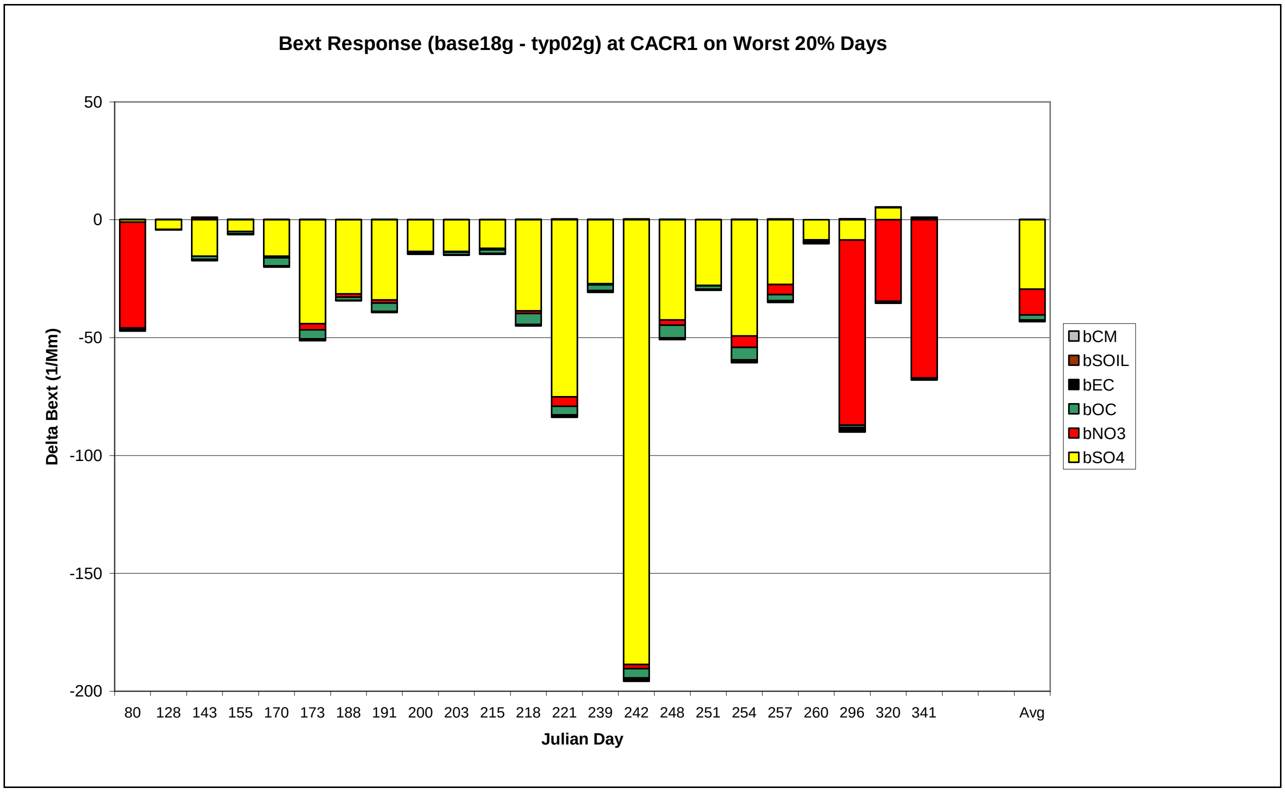

Figure 4-3d. Differences in Modeled 2002 and 2018 Base G CMAQ Results (2018-2002) Daily Extinction for Caney Creek (CACR), Arkansas and Worst 20 Percent (W20%) Days in 2002.

4.4.2 Summary 2018 Visibility Projections Across Class I Areas

Figure 4-4 displays a "DotPlot" of 2018 visibility projections using the 2002 Typical and 2018 base case Base G CMAQ 36 km modeling results. DotPlots present the 2018 visibility projections as a percentage of meeting the 2018 URP point. For example, at CACR the 2018 Base G modeling achieved 112% of the visibility reduction needed to meet the 2018 URP point so the dot under CACR is plotted at 112%. Class I areas' with dots above 100% surpass the 2018 URP point (i.e., are below the glidepath), whereas Class I areas' with dots that are under 100% fail to meet the 2018 URP point. Figure 4-4 summarizes the 2018 visibility projections using the EPA default "Regular RRF" and the two alternatives where CM is assumed to be natural (CM RRF=1) and both CM and Soil are assumed to be natural (CM&SOIL RRF=1). When CM or CM&SOIL are assumed to be natural that means that we assume the same CM or CM&SOIL occurs in the 2018 future-year as in the 2000-2004 Baseline Conditions. For the CENRAP sites, the EPA default and alternative projection, assuming CM alone or CM and Soil are natural, techniques produced similar results.

At the four eastern CENRAP Class I area sites close to the Mississippi River (CACR, UPBU, HEGL and MING), the 2018 visibility projections meet (HEGL) or surpass the 2018 URP point. Breton Island Class I area (BRET) comes up 6% short of meeting the 2018 URP point (i.e., 94% of the URP point). Wichita Mountains Class I area (WIMO) comes up approximately 40% short of the 2018 URP point. The two northern Class I areas (BOWA and VOYA) also come up about 40% short of meeting the 2018 URP point (i.e., achieve 69% and 53% of the visibility improvement needed to meet the 2018 URP point). The two Texas Class I areas only achieve

26% (BIBE) and 34% (GUMO) of the visibility improvement needed to meet the 2018 URP point for the worst 20 percent days. As discussed in more detail in Chapter 5, much of the difficulty for the Texas and some of the other CENRAP Class I areas in meeting the 2018 URP point is due to large contributions due to international transport, much of which (e.g., Mexico and global transport) is assumed to remain unchanged from 2002 to 2018.

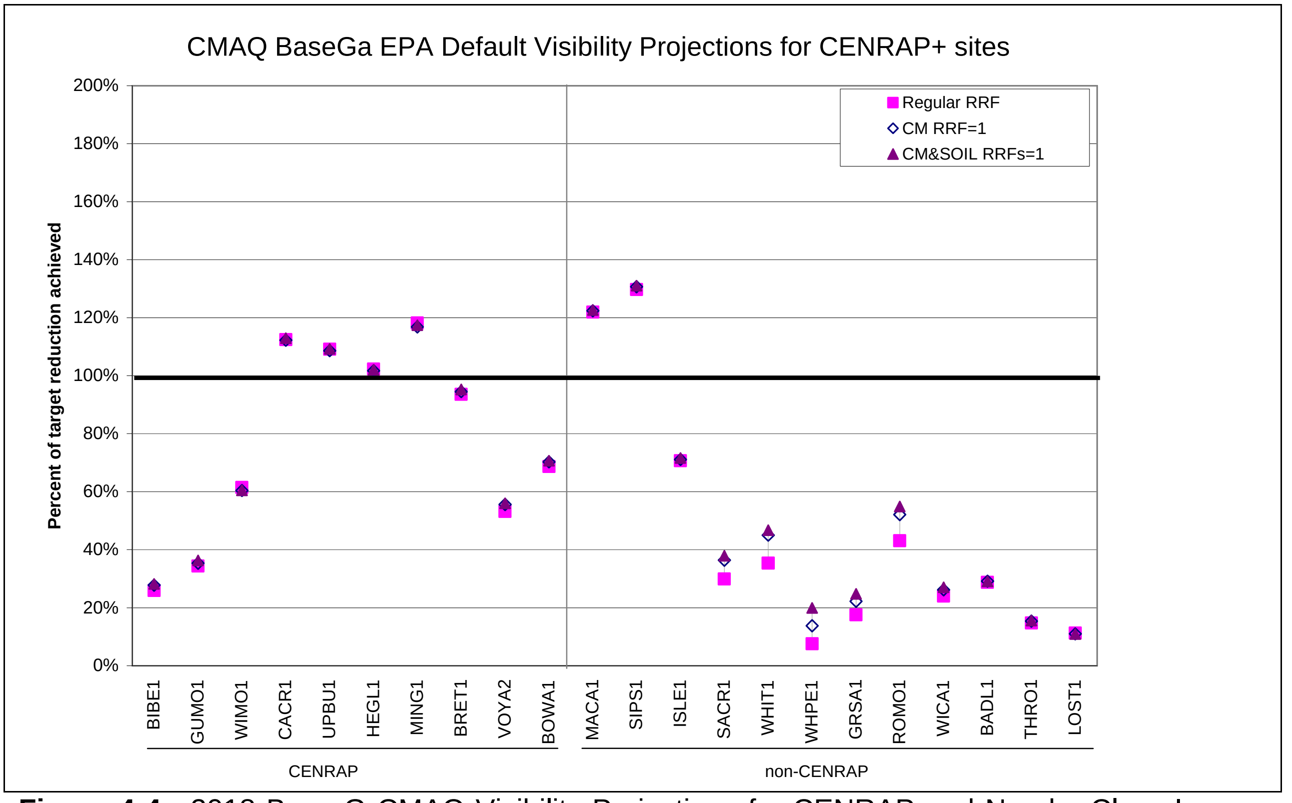

Figure 4-4. 2018 Base G CMAQ Visibility Projections for CENRAP and Nearby Class I areas Using DotPlots that Express 2018 Visibility as a Percentage of Meeting the 2018 URP Point On the Deciview Linear Glidepath.

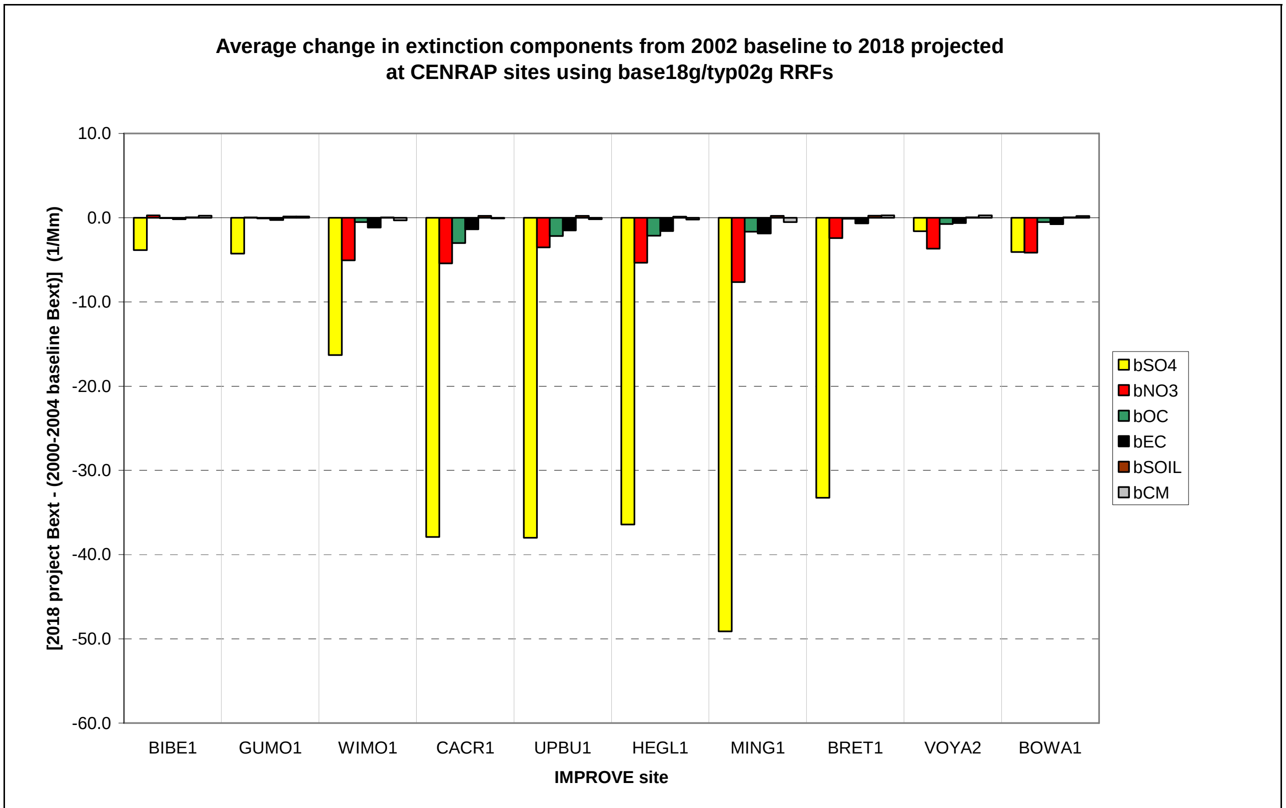
Figure 4-5 displays the model estimated absolute change in extinction (Mm^{-1}) averaged across the 2002 worst 20 percent days at Class I areas in and near the CENRAP region. The largest modeled reductions are in SO4 extinction. Figure 4-6 displays the percent change in the projected PM extinction by PM species for each CENRAP and nearby Class I area average across the worst 20 percent days (i.e., the relative modeled change). The four CENRAP Class I areas that meet the 2018 URP point (CACR, UPBU, HEGL and MING) are characterized by large SO4, NO3 and EC extinction reductions (30-40%) with small Soil increases. At the other CENRAP Class I areas, however, there are lower levels of SO4, NO3 and EC extinction reductions and even some NO3 increases (BIBE). At the non-CENRAP Class I areas, the two VISTAS Class I areas (MACA and SIPS) have large reductions in SO4 extinction (~50%), whereas the WRAP Class I areas SO4 extinction reductions are much smaller.



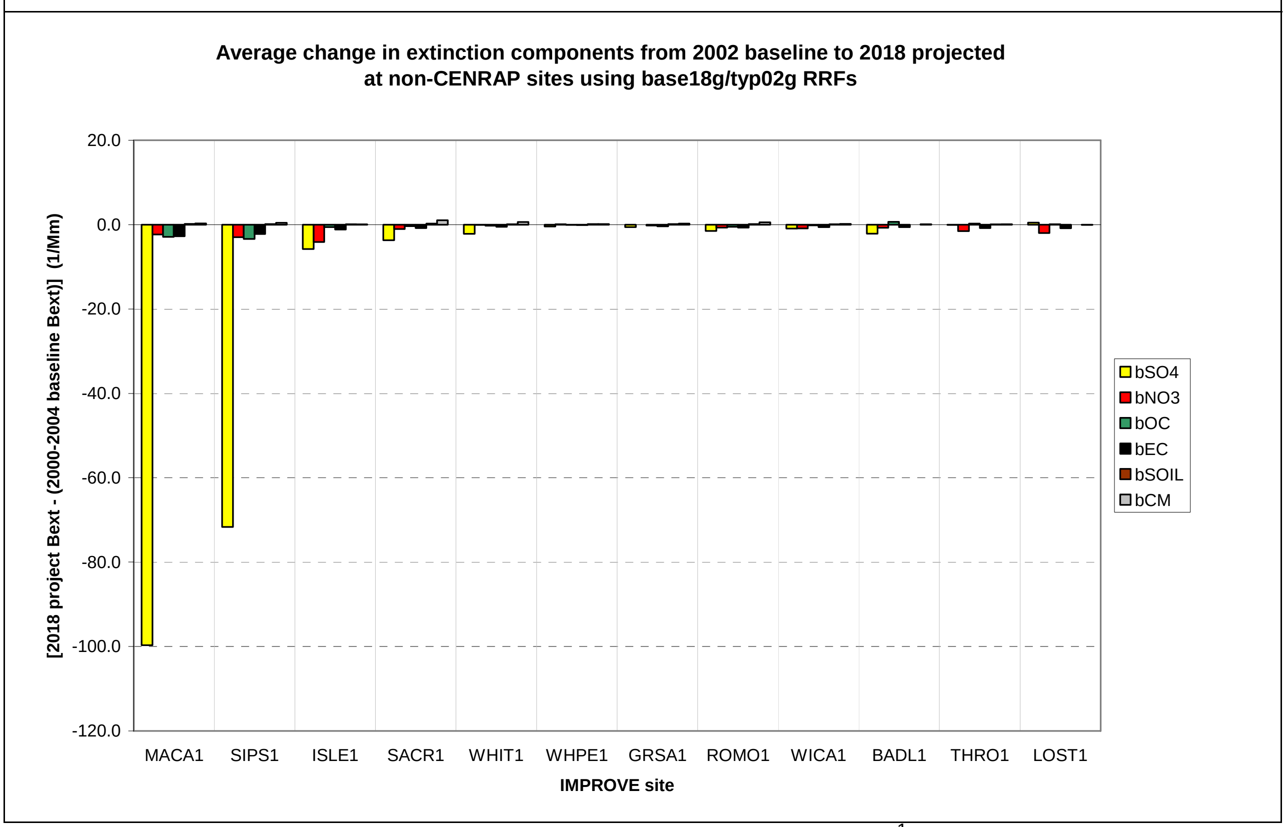


Figure 4-5. Absolute Model Estimated Changes in Extinction (Mm^{-1}) by PM Species for Class I Areas in the CENRAP region (top) and Near the CENRAP region (bottom).

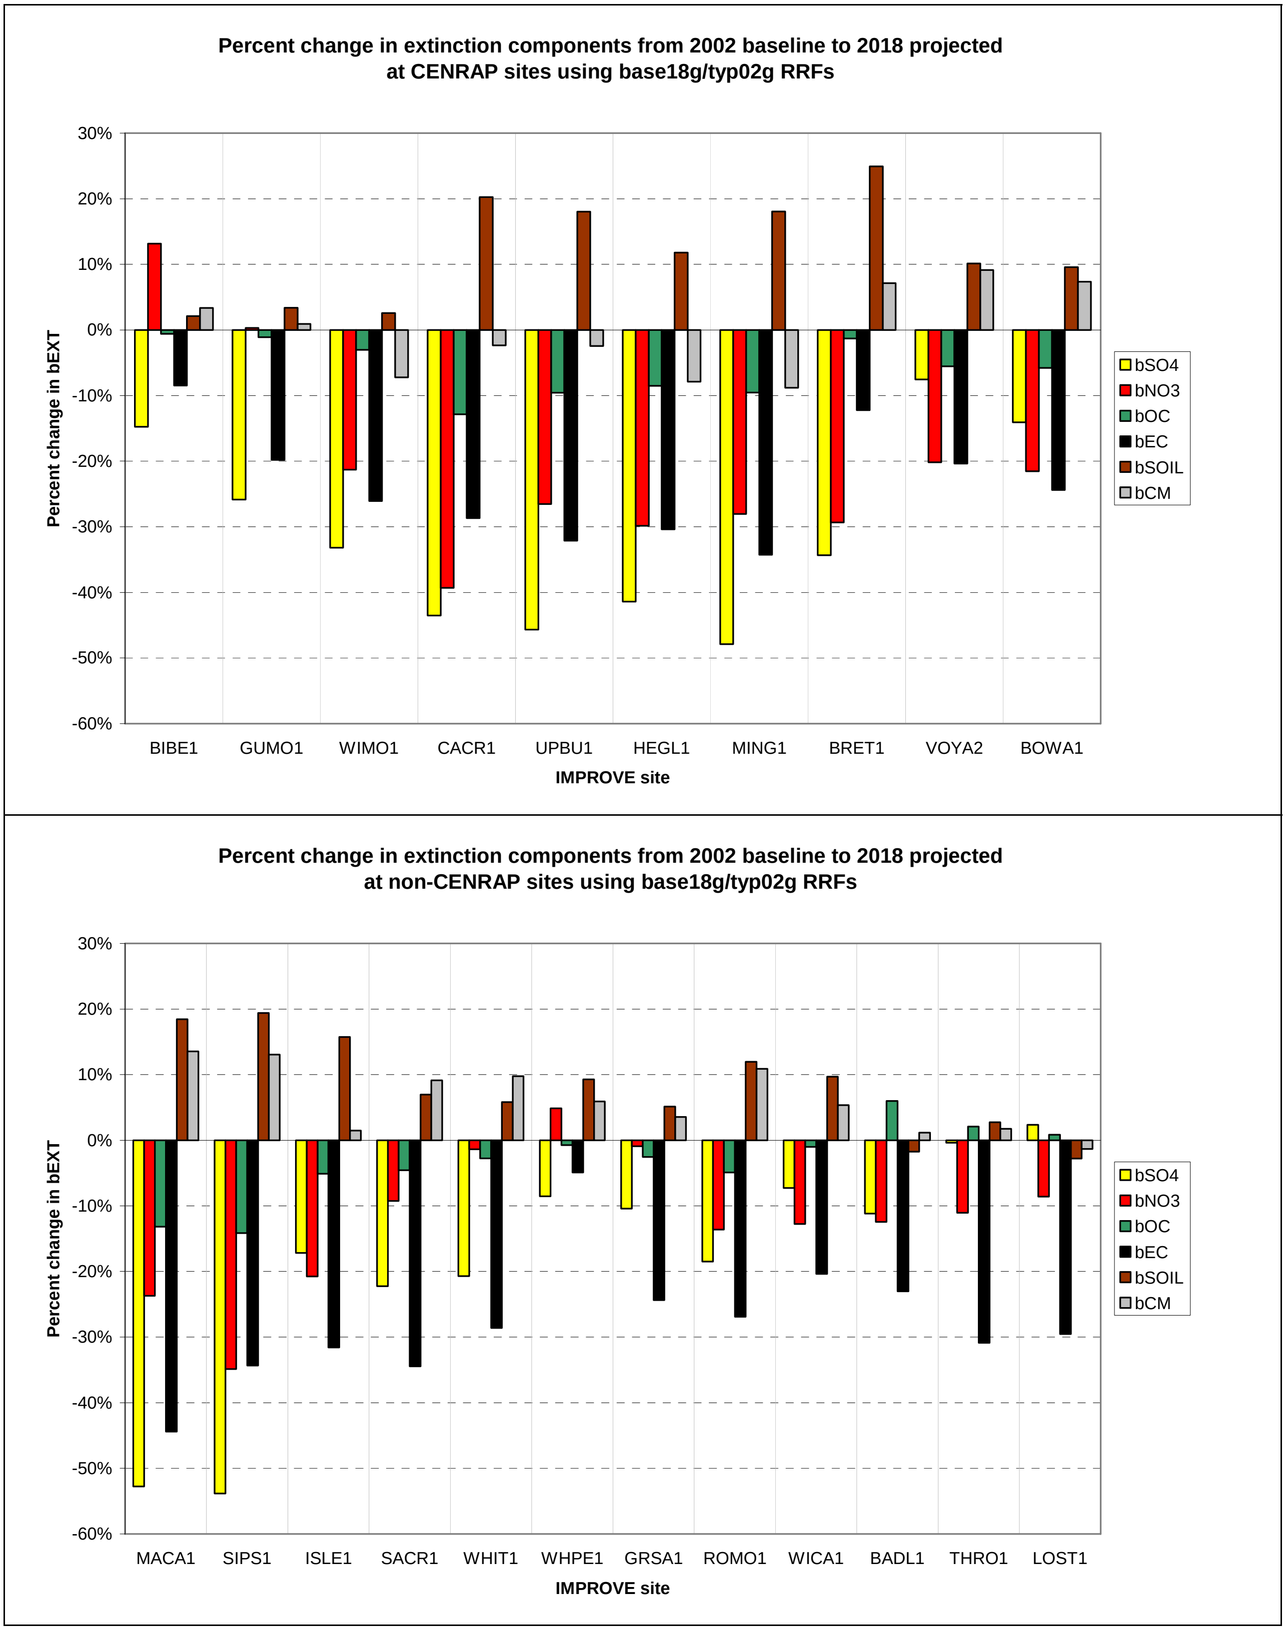

Figure 4-6. Percent Change In Modeled Extinction by PM Species Averaged Across the 2002 Worst 20 Percent Days for Class I areas in the CENRAP region (top) and Near the CENRAP region (bottom).

4.5 2018 Visibility Projections for Base G C1 Control Scenario

The 2018 visibility projections based on the CMAQ simulations for the 2018 Base G C1 Control Strategy simulations are presented in this section. The C1 Control Strategy results in reductions mainly in SO2 and NOx emissions from point sources in the CENRAP states. Consequently, PM improvements are limited to mainly SO4 and NO3 concentration reductions in the CENRAP states. Figure 4-7 displays the differences in CMAQ-estimated annual average SO4 and NO3 concentrations between the 2018 Base G base case and the 2018 Base G C1 Control Strategy case; the differences in all other PM species (with the exception of NH4) were negligible (see: http://pah.cert.ucr.edu/aqm/cenrap/cmaq.shtml#base18gc1vsbase18g). Annual average SO4 concentration reductions of over a quarter of a $\mu g/m^3$ are estimated to occur in northeast Texas, east Oklahoma, Missouri, northeast Arkansas and up into Iowa and Illinois. There are much lower reductions in NO3 that cover a similar area.

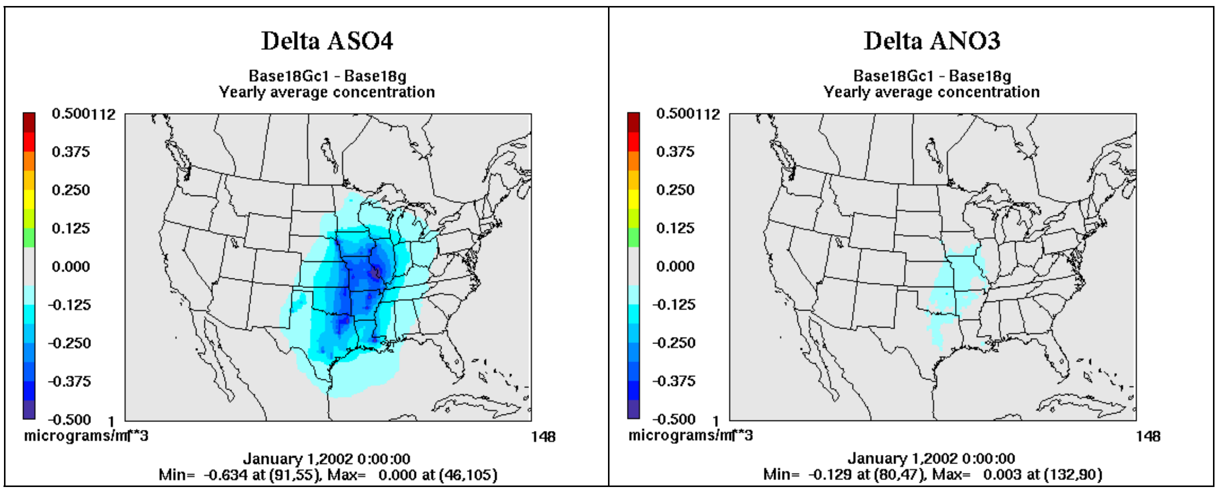

Figure 4-7. CMAQ-Estimated Reductions in Annual Average SO4 (left) and NO3 (right) Fine Particle Concentrations Between the 2018 Base G Base Case and 2018 Base G C1 Control Strategy Case.

Figure 4-8 displays the DotPlot comparisons of the 2018 visibility projections for 2018 Base G and 2018 Base G C1 Control Strategy emission scenarios. The additional controls in the C1 Control Strategy are projected to result in visibility improvements for the worst 20 percent days at Class I areas throughout and near the CENRAP region. Sites are closer to being on the glide path by 10 to 30 percent. For Breton Island this makes a difference of not meeting the 2018 URP point in 2018 Base G (94%) to surpassing the URP point in the C1 Control Strategy (106%).

Table 4-4 presents a tabular summary of the information presented in Figure 4-8, including the Baseline, 2018 URP point, and 2018 projected visibility for the Base G and C1 Control Strategy simulations.

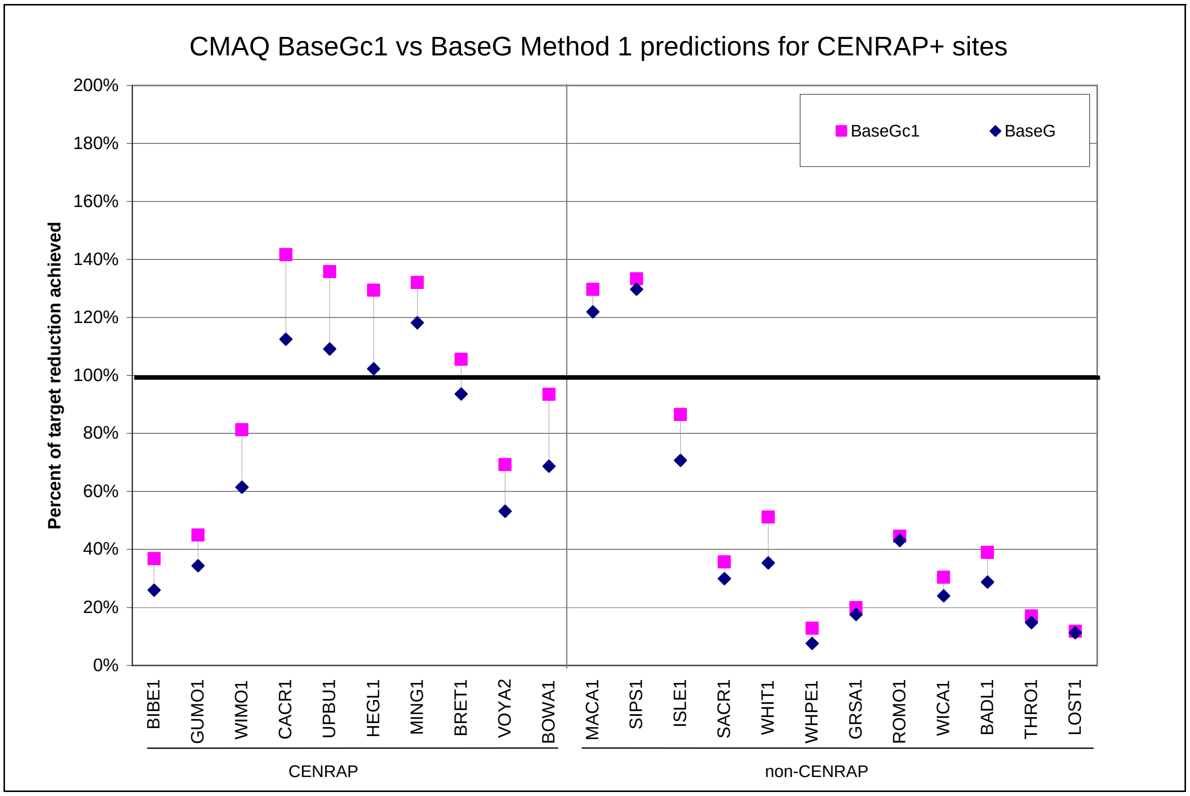

Figure 4-8. 2018 Visibility Projections as a Percentage of Meeting the 2018 URP Point (i.e., DotPlot) for the 2018 Base G and 2018 Base G C1 Control Strategy Emission Scenarios.

Table 4-4. 2000-2004 Baseline, 2018 URP Point, and Projected 2018 Visibility and Percent of Meeting the 2018 URP Point for the 2018 Base G and 2018 C1 Control Strategy CMAQ Simulations.

5.0 ADDITIONAL SUPPORTING ANALYSIS

This Chapter presents additional supporting analysis to the modeled 2018 visibility projections provided in Chapter 4. This supporting analysis may be used by the states in their RHR SIPs, along with their factor analysis, to assist in setting their 2018 RPGs for the worst 20 percent days and best 20 percent days.

5.1 Comparison of CENRAP 2018 Visibility Projections with Other Groups

2018 visibility projections for CENRAP and nearby Class I area have also been performed by the other RPOs. Thus, it is useful to compare the CENRAP 2018 visibility projections with those from the other RPOs as a quality assurance (QA) check and to foster confidence in the CENRAP modeling results.

5.1.1 Comparison of CENRAP, VISTAS, MRPO and WRAP Visibility Projections

The CENRAP 2018 Base G visibility projections were compared to the following other RPO visibility projections:

- VISTAS 2018 visibility projections based on their CMAQ 12 km 2002 annual modeling results for the 2002 Base G and 2018 Base G2a emissions scenarios.
- MRPO 2018 visibility projections based on their CAMx 36 km 2002 annual modeling for the Run 4 Scenario 1a (R4S1a) emissions scenario.
- WRAP 2018 visibility results based on their Plan02b and Base18b CMAQ 36 km modeling of the 2002 calendar year.

Figure 5-1 displays a DotPlot comparison of the four RPO visibility projections expressed as a percentage of achieving the 2018 URP point at CENRAP and nearby Class I areas. For the four CENRAP Class I areas just west of the Mississippi River in Arkansas and Missouri (CACR, UPBU, HEGL and MING), 2018 visibility projections are available from the CENRAP, VISTAS and MRPO RPOs. At HEGL, the three RPOs 2018 visibility projections are in close agreement with each other (estimated to achieve 99%, 101% and 95% of the 2018 URP point). The CENRAP and VISTAS 2018 visibility projections are also very close at the other three Arkansas-Missouri CENRAP Class I areas: CACR (112% and 116%), UPBU (109% and 112%) and MING (118% and 114%). But the MRPO 2018 visibility projections are approximately 12 to 25 percentage points lower than the CENRAP and VISTAS projections at these three Class I areas, with values of 97% to 100%. The reasons why the MRPO 2018 visibility projections are less optimistic than CENRAP and VISTAS are unclear. However, the MRPO focused on visibility projections at their northern Class I areas and likely did not use the latest CENRAP emission estimates. In addition, the CENRAP 2018 visibility projections included BART controls on several sources in CENRAP states not included in the MRPO projections. Such BART controls are even more important in those states not covered by CAIR.

For the Breton Island (BRET) Class I area, 2018 visibility projections are available from CENRAP and VISTAS. CENRAP estimates that BRET will achieve 94% of the URP point and

VISTAS is slightly less optimistic with an 84% value. One potential contributor to this is that emissions from off-shore marine vessel emissions in the oil and gas production areas of the Gulf of Mexico are double counted in the VISTAS Base G modeling. As these emissions were assumed to remain unchanged between 2002 and 2018, the double counting of their emissions will result in stiffer RRFs than there should be and consequently less visibility benefits in 2018. This double counting also occurred in the CENRAP Base F modeling but was corrected in Base G. The double counting occurred because off-shore marine vessels were present in both the MMS off-shore oil/gas development inventory for the Gulf of Mexico and the VISTAS off-shore marine vessel inventory for the Pacific and Atlanta Oceans and the Gulf of Mexico. VISTAS intends to correct this double counting in their next round of modeling.

At the two northern Minnesota Class I areas (BOWA and VOYA), the MRPO 2018 visibility projections (93% and 92%) exhibit more visibility improvements than CENRAP's (69% and 53%). This is believed to be due to higher contributions to visibility impairment from Canada in the CENRAP modeling. Figure 5-2 displays the CENRAP 2002 Base F total SO2 emissions and their differences with the 2018 Base F SO2 emissions. The SO2 emissions in Alberta Canada appear to be much higher and more wide spread when compared to the other provinces in Canada and emissions in the U.S. states. Also, there is a very large SO2 source in northern Manitoba (> 10^5 tons/year). The Alberta SO2 emissions may be overstated in the CENRAP modeling, which would overstate the Canadian contribution to visibility impairment. The western boundary of the MRPO modeling domain was east of the Rocky Mountains so did not include Alberta. CENRAP confirmed that the Alberta emissions and the source in Manitoba were present in the emissions provided by Canada. Air parcels from Canada are generally associated with clean visibility conditions at the northern Minnesota Class I areas with the worst 20 percent days generally occurring under conditions with a southerly wind component. However, in 2002 some of the worst 20 percent days did occur with transport out of Canada. For example, Figure 5-3 displays back trajectories off of the VIEWS website for two of the worst 20 percent days at Voyageurs National Park (Julian Days 347 and 332). These back trajectories suggest that the potentially overstated emissions in Alberta would have an impact at VOYA during the worst 20 percent days in 2002.

At the VISTAS Mammoth Cave (MACA), Kentucky Class I area, VISTAS, CENRAP and the MRPO estimated that 2018 visibility for the worst 20 percent days will achieve, respectively, 122%, 123% and 102% of the 2018 URP point. The close agreement between the VISTAS (122%) and CENRAP (123%) 2018 visibility projections for MACA is encouraging. Why MRPO is 20 percentage points lower is unclear, but may be due to using earlier versions of the VISTAS and CENRAP emissions. The 2018 visibility projections at Sipsey (SIPS), Alabama estimated by VISTAS (127%) and CENRAP (130%) are also extremely close.

Both the CENRAP and WRAP 2018 visibility projections agree that the WRAP Class I areas fail to achieve the 2018 URP point by a wide margin, with values achieving only ~40% or less of the 2018 URP point. The CENRAP 2018 visibility projections agrees well with the WRAP values at Great Sands (GRSA), Colorado (18% vs. 15%), Badlands (BADL), South Dakota (24% vs. 31%), Theodore Roosevelt, North Dakota (15% vs. 11%) and Lostwood (LOST), Montana (11% vs. 14%). There is also reasonable agreement between CENRAP and WRAP 2018 visibility projections at Salt Creek (SACR), New Mexico (30% vs. 12%), Rocky Mountain (ROMO), Colorado (43% vs. 30%), and Wind Cave (WICA), South Dakota (24% vs. 6%). There are two WRAP Class I areas, White Mountains (WHIT) and Wheeler Peak (WEPE), where the WRAP

2018 visibility projections estimate that visibility will degrade for the worst 20 percent days (i.e., negative percent of achieving the 2018 URP point), whereas CENRAP estimates visibility improvements. The reasons for these differences are unclear.

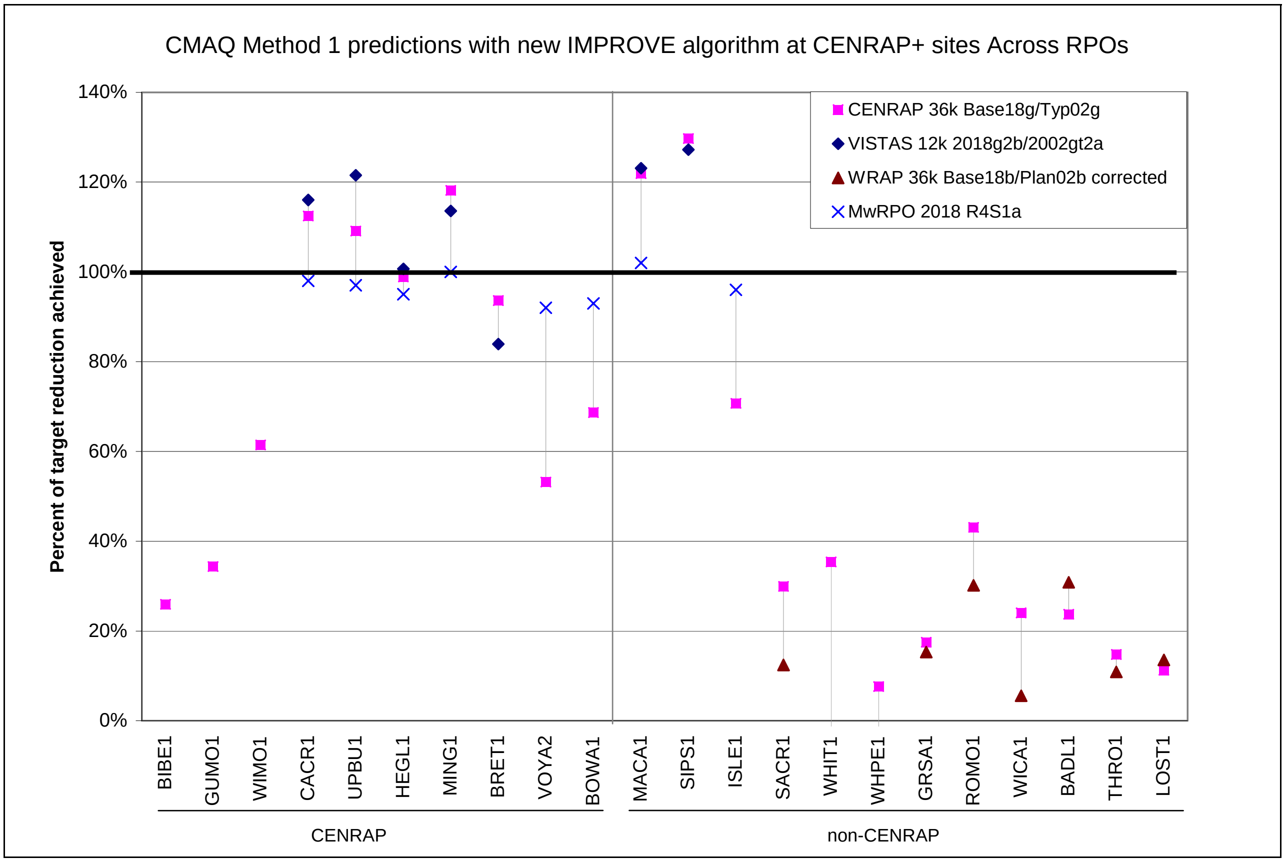

Figure 5-1. DotPlot comparing the CENRAP, VISTAS, MRPO and WRAP 2018 visibility projections expressed as a percentage of achieving the 2018 URP goal.

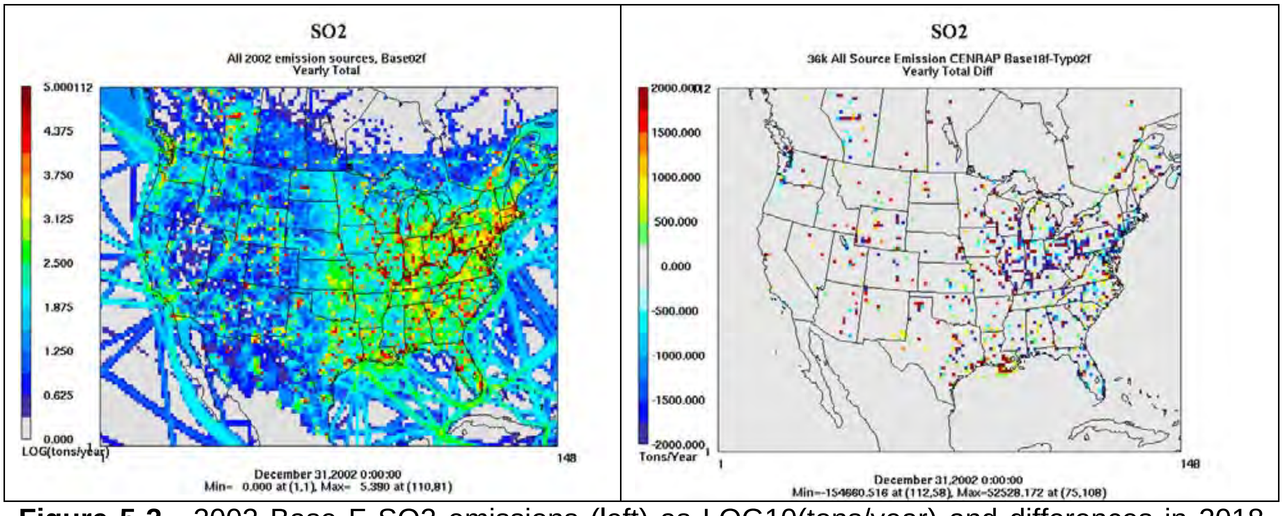

Figure 5-2. 2002 Base F SO2 emissions (left) as LOG10(tons/year) and differences in 2018 and 2002 Base F SO2 emissions (tons/year).

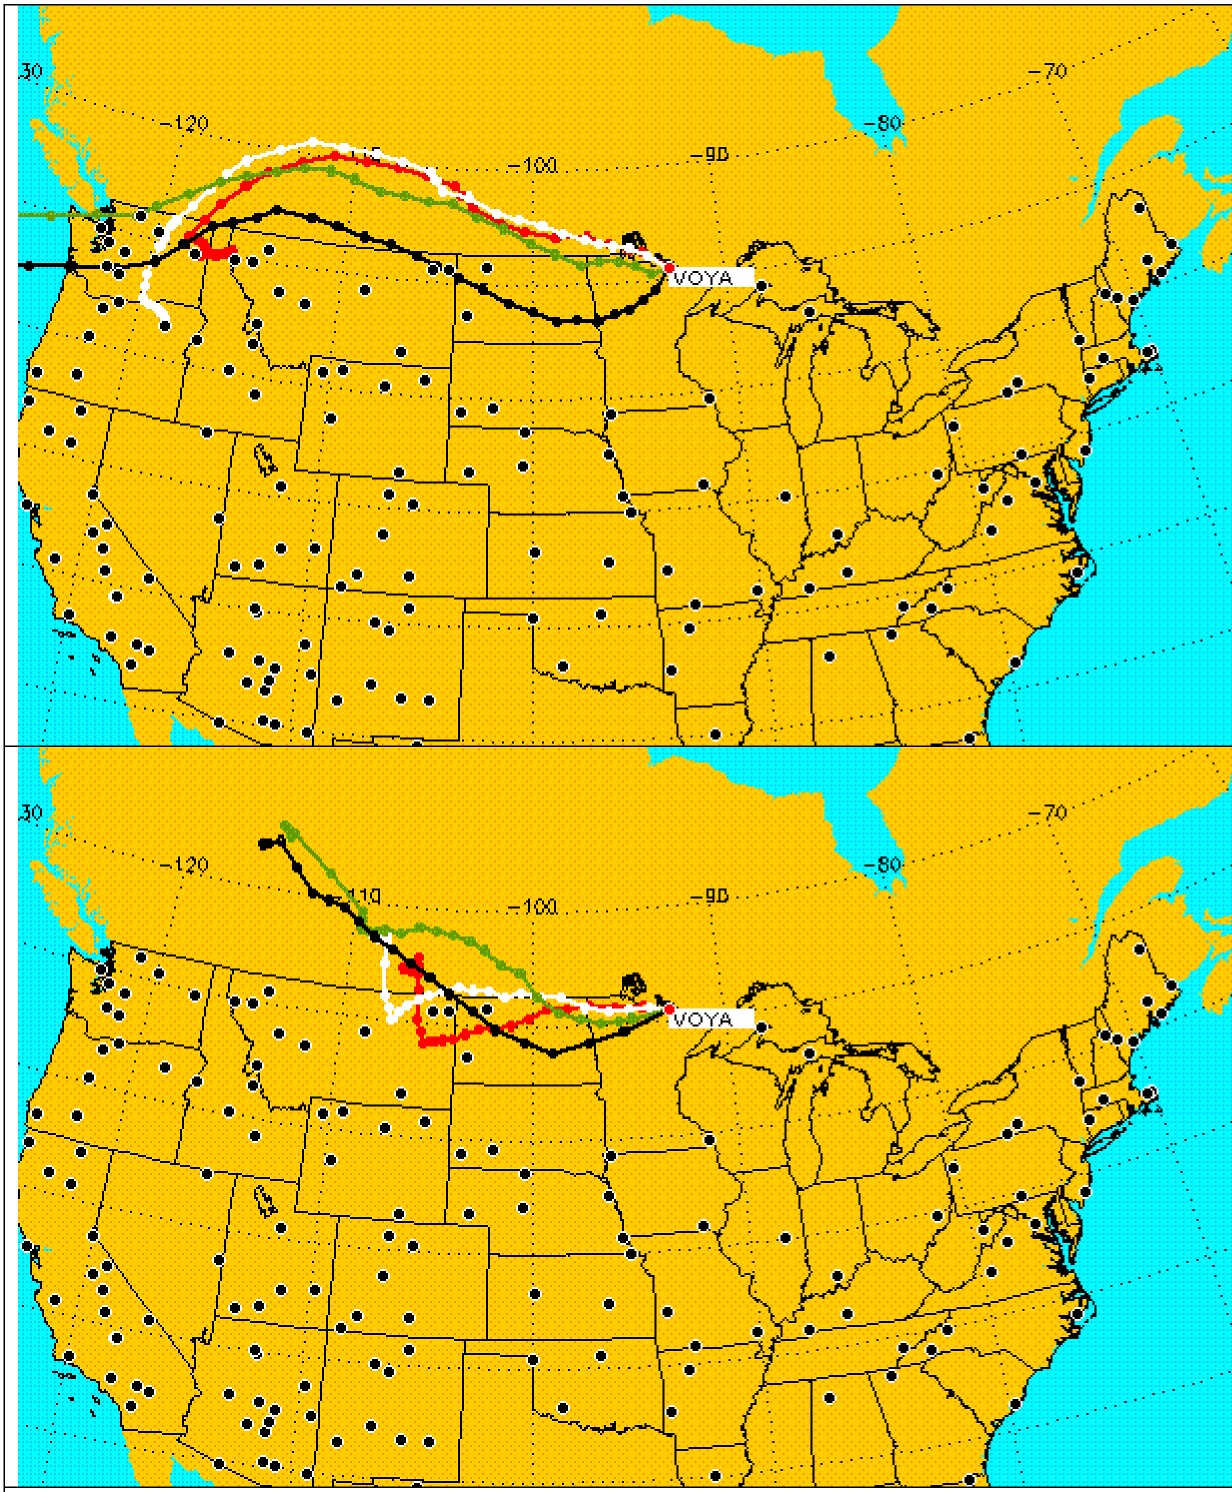

Figure 5-3. Exampled back trajectories to Voyageurs National Park for two of the worst 20 percent days from 2002: December 13, 2002 (Julian Day 347) and November 28, 2002 (Julian Day 332).

5.2 Extinction and PM Species Specific Visibility Projections and Comparisons to 2018 URP Point

It is useful to examine 2018 visibility projections by PM species to determine how each PM component of visibility is changing as both a diagnostic analysis of the visibility projections as well as whether species that are associated more with anthropogenic emissions (e.g., SO4 and NO3) are being reduced substantially compared to those that are less influenced by anthropogenic emissions (e.g., Soil and CM). However, because deciview is the natural logarithm of total extinction, such comparisons can not be made using the deciview scale and must be made using extinction. The linear glidepath from which the 2018 URP points are derived are based on deciview, thus to examine corresponding glidepath using extinction the curvature associated with the logarithmic transformation of the linear deciview glidepath to extinction must be accounted for in the extinction glidepath.

5.2.1 Total Extinction Glidepaths

Figure 5-4 displays a total extinction based glidepath for Caney Creek that is based on the EPA default deciview linear glidepath counterpart shown in Figure 4-3a. That is, the deciview linear glidepath defined by the line connecting the 26.36 dv Baseline Conditions at 2004 to the 11.58 dv Natural Conditions in 2064. The glidepath points in 2008, 2018, 2028, etc. from the linear deciview glidepath (Figure 4-3a) are turned into extinction (Bext) [Bext = 10 exp(dv/10)] to create the curved extinction glidepath that exactly match the linear deciview glidepath points. Note that the 2000-2004 Baseline using the curved extinction glidepath is slightly different than if you just converted the deciview baseline to extinction because the logarithm relationship is performed before the averaging, but they are extremely close. Using the extinction curved glidepath, the 2018 URP point is a reduction of the Baseline 145.10 Mm^{-1} to 98.88 Mm^{-1} (a 46.22 Mm^{-1} reduction). The modeled 2018 visibility projection in extinction is 97.54 Mm^{-1}, a 47.56 Mm^{-1} reduction, which achieves 103% of the reduction needed to achieve the 2018 URP point. Note that this compares with achieving 112% of the 2018 URP reduction point when using the deciview linear glidepath. The percent of achieving the 2018 URP point using the linear deciview and curved extinction glidepaths will rarely be the same due to the logarithmic relationship between the two visibility metrics and the fact that averaging within and across years in the deciview calculations occur after the logarithms have been applied. The greater the difference in extinction across the worst 20 percent days in a year and averaged across the years in the 2000-2004 Baseline and the greater number of years available from the 2000-2004 Baseline may result in greater differences in the 2018 URP points using the linear deciview and the curved extinction glidepaths.

Appendix F contains total extinction curved glidepaths for all the CENRAP Class I areas and Figure 5-5 contains a DotPlot that compares the percent of achieving the 2018 URP point at each CENRAP Class I area using the 2018 Base G modeling results and the linear deciview and curved extinction glidepaths. At most CENRAP Class I areas the ability of the 2018 modeling results to achieve the 2018 URP point is the same using either the deciview or extinction glidepaths. There are some differences at GUMO, BOWA and VOYA Class I areas which are due to these Class I areas having more complete data during the 2000-2004 Baseline period and therefore more years in the Baseline than other Class I areas as well as having variations in extinction across the worst 20 percent days and years (Appendix F). In any event, the closeness of the ability of the model to achieve the 2018 URP point using either the extinction or deciview

glidepath verifies the validity of the extinction based glidepaths and allows for the construction of PM species specific glidepaths in extinction to gain insight into how each component of extinction is being reduced to achieve a uniform rate of progress toward natural conditions in 2064.

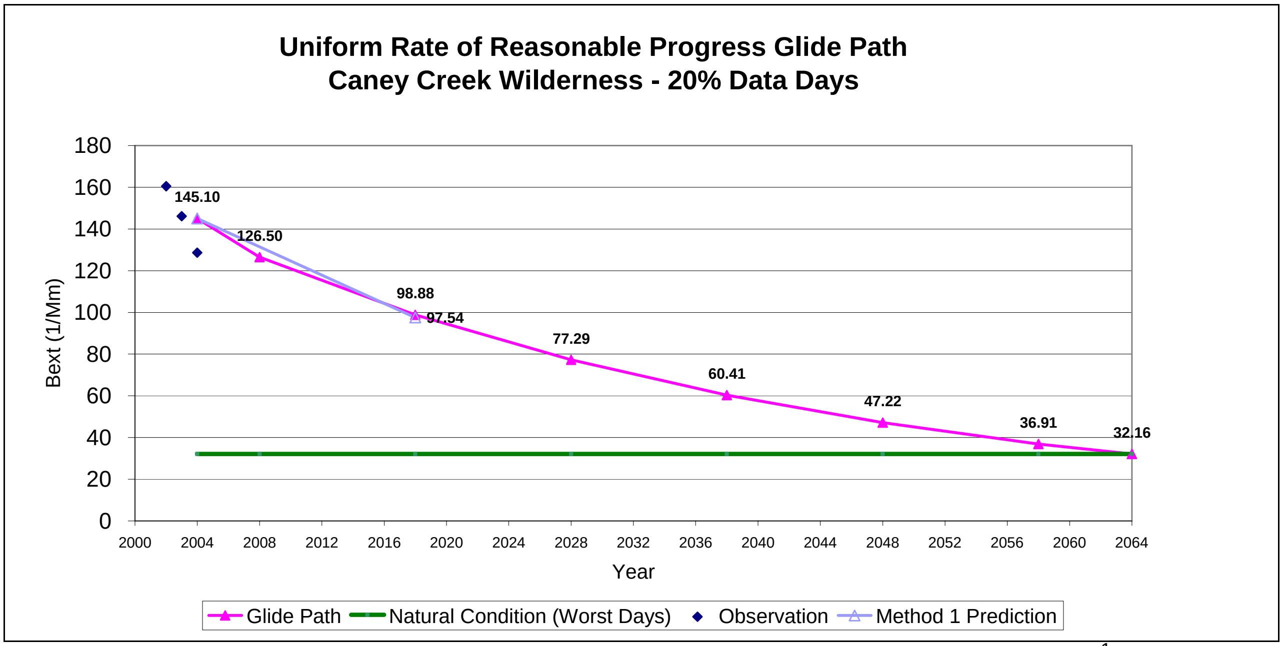

Figure 5-4. 2018 Visibility Projections and 2018 URP Glidepaths in extinction (Mm^{-1}) for Caney Creek (CACR), Arkansas and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

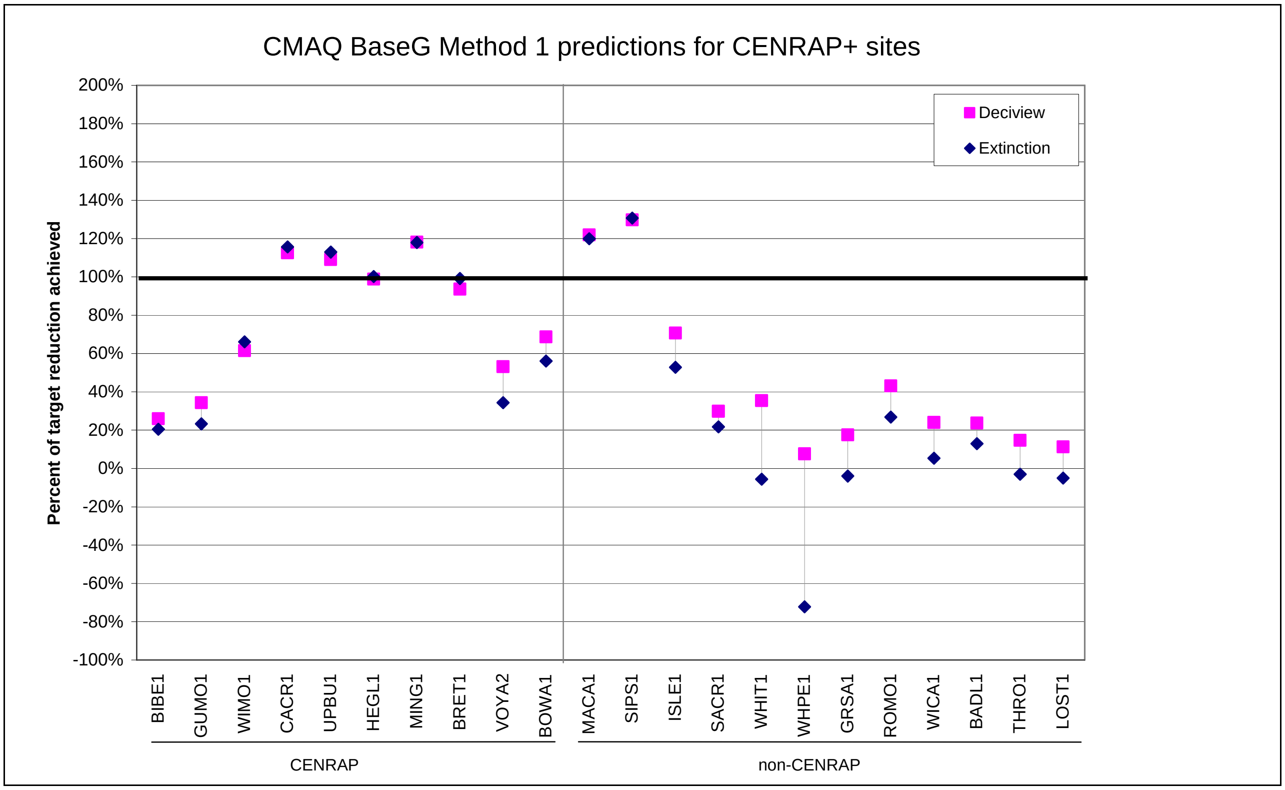

Figure 5-5. CMAQ 2018 Base G visibility projections and comparison of ability to achieve the 2018 URP point using the EPA default deciview and alternative total extinction Glidepaths.

5.2.2 PM Species specific Glidepaths

The VIEWS website (http://vista.cira.colostate.edu/views/) has posted PM species specific Natural Conditions based on the new IMPROVE equation. Using these PM species specific Natural Conditions and the curved extinction glidepaths we can evaluate how well visibility extinction achieves the 2018 URP point on a species-by-species basis. The PM species specific glidepaths are constructing starting with a Baseline at 2004 averaging the extinction for each PM species measured using the 2000-2004 IMPROVE observations and ending with the Natural Conditions in 2064 from the VIEWS website. Points in the glidepath for the years in between 2004 and 2064 are constructed based on the relative differences in the 2004 Baseline and 2064 Natural Conditions PM species extinction such that the total extinction due to all PM species at each interim year adds up to the same as the total extinction on the extinction-based glidepath (e.g., Figure 5-3). For example, for the CACR SO4 extinction glidepath the 2018 URP point is generated from the 2004 and 2064 SO4 extinction (BSO4) and the 2004, 2018 and 2064 total extinction (BTOT) as follows:

$$
\begin{aligned}
BSO4\_2018 &= BSO4\_2004 - [(BSO4\_2004 - BSO4\_2064)/ \\
&\quad (BTOT\_2004 - BTOT\_2064)] \times (BTOT\_2004 - BTOT\_2018) \\
&= 87.05 - [(87.05 - 3.20)/(145.10 - 32.16)] \times (145.10 - 98.88) \\
&= 52.73\ Mm^{-1}
\end{aligned}
$$

Note that the SO4 2018 URP point in Figure 5-5 and F-1b (52.77 Mm-1) does not exactly match the 52.73 Mm^{-1} calculated due to round off error in the above calculation that only used numbers with precision to the nearest hundredth.

As there are larger differences between the Baseline and Natural PM species extinction for some species, then the rate of improvement to achieve a species specific 2018 URP point will vary across PM species. For example, current Baseline extinction values for Soil and CM tend to be closer to Natural Conditions than extinction due to SO4 and NO3. Consequently the rate of progress to achieve the 2018 URP point for Soil and CM will be less than for SO4 and NO3.

Appendix F contains the PM species specific glidepaths compares them to the modeled 2018 projections for all CENRAP Class I areas. The species specific results for the CACR Class I area in Figure F-1 are reproduced in Figure 5-6. The modeled rate of SO4 and NO3 extinction reduction is greater than the PM species specific glidepaths and both achieve the species specific 2018 URP point by achieving 111% and 104% of the reduction needed to achieve the 2018 URP point. The modeled rate of extinction improvement at CACR for EC and OC is less than the species specific glidepath achieving only 65% and 75% of the reduction needed to achieve the species specific 2018 URP point. The PM species specific glidepath for Soil is flat because the Baseline and Natural Conditions (1.12 Mm^{-1}) are the same. This does not mean that anthropogenic emissions of Soil do not contribute on worst 20 percent days at CACR. It just points to a mismatch between the current set of worst 20 percent days and those in 2064 under Natural Conditions. The worst 20 percent days in 2064 under Natural Conditions will be dominated by wind blown dust days when Soil and CM may be higher than during the current set of worst 20 percent days that are dominated by SO4, NO3 and OMC. Thus, the Soil and CM glidepaths tend to be flatter and in some cases may even have an upward trend for some Class I areas (see Appendix F). Soil is projected to increase at CACR in 2018 so does not achieve its species specific URP point. Little reduction in CM is also seen by 2018. As discussed

previously, this is due in part to incompatibilities between the measured Soil and CM values at the IMPROVE monitor and the modeled Soil and CM species. In the model, a large component of the Soil and CM in the inventory is due to paved and unpaved road dust. These emissions are directly related to Vehicles Miles Traveled (VMT). VMT is projected to increase in future-years resulting in increases in road dust emissions. At the IMPROVE monitor, much of the measured Soil and CM is likely due to local dust events that are not simulated by the model using a 36 km grid resolution. Thus, the 2018 projections for Soil and CM are likely applying modeled changes due to road dust to local Soil and CM concentrations that in reality are likely natural and should remain unchanged in the future year. This is why alternative 2018 modeled projection approaches have been developed that assume that CM and CM and Soil are natural so remain unchanged in the future-year (see Section 5.5).

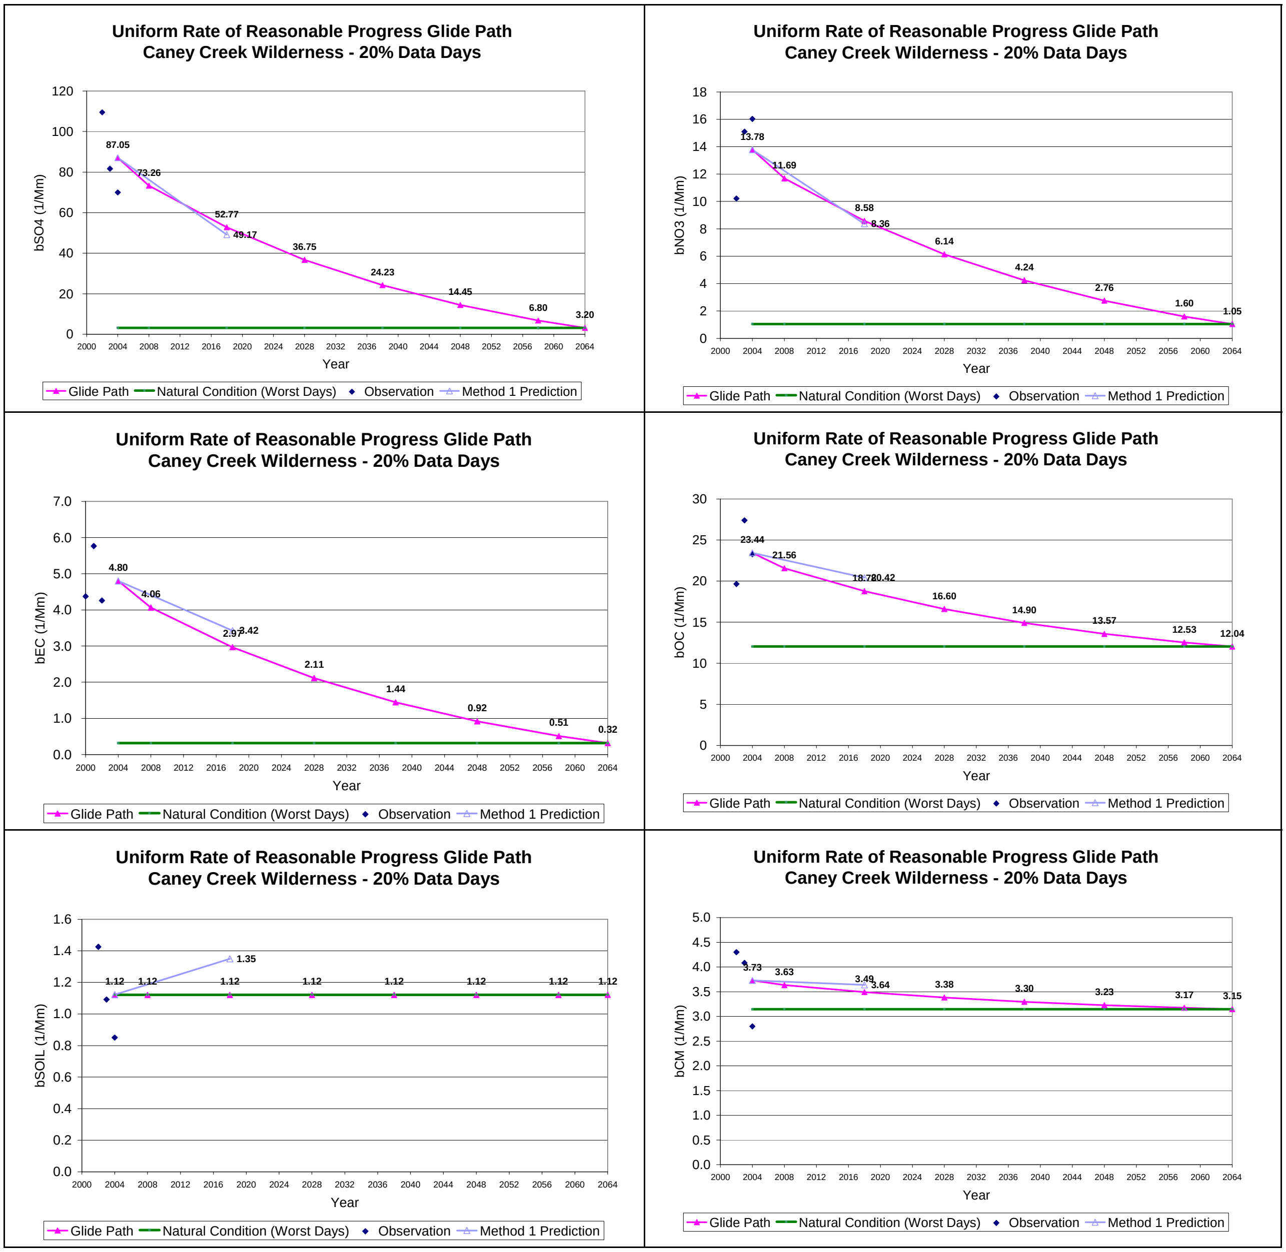

Figure 5-6. 2018 Visibility Projections and 2018 URP Glidepaths for SO4 (top left), NO3 (top right), EC (middle left), OMC (middle right), Soil (bottom left) and CM (bottom right) in extinction (Mm^{-1}) for Caney Creek (CACR), Arkansas and Worst 20 Percent Days using 2002/2018 Base G CMAQ 36 km modeling results.

Figure 5-7 displays a DotPlot that compares the 2018 projected total and PM species specific extinction with the 2018 URP points. These results show that SO4 is most frequently achieving its 2018 URP point at those Class I areas that achieve the deciview URP point. Reductions in NO3 and EC also sometimes achieve their species specific URP point.

There are some anomalies in the species specific projections and glidepaths that bear mention and point to areas where better estimates of emissions growth and Natural Conditions are needed needed. The increase in 2018 Soil projections is not an isolated incident at CACR and occurs at other CENRAP Class I areas. There are three CENRAP Class I areas that "achieve" the Soil specific 2018 URP point (HEGL, BOWA and VOYA). An examination of these glidepaths and visibility projections (Figures F-4f, F-5f and F-6f) reveals that the current Baseline Conditions Soil at these three Class I areas is actually less than the 2064 Natural Conditions so that the glidepath is an accent rather than reduction (Figures F-4g, F-5g and F-6g). In these three cases to "achieve" the 2018 URP point the modeling results must increase the projected Soil extinction, which is why these three Class I areas "achieve" their 2018 URP point for Soil. Clearly, the 2018 URP point for Soil is not very meaningful under these conditions. The current Baseline Conditions for OMC at BRET and BOWA is also less than the Natural Conditions resulting in anomalous glidepaths (Figure F-3e and F-4e).

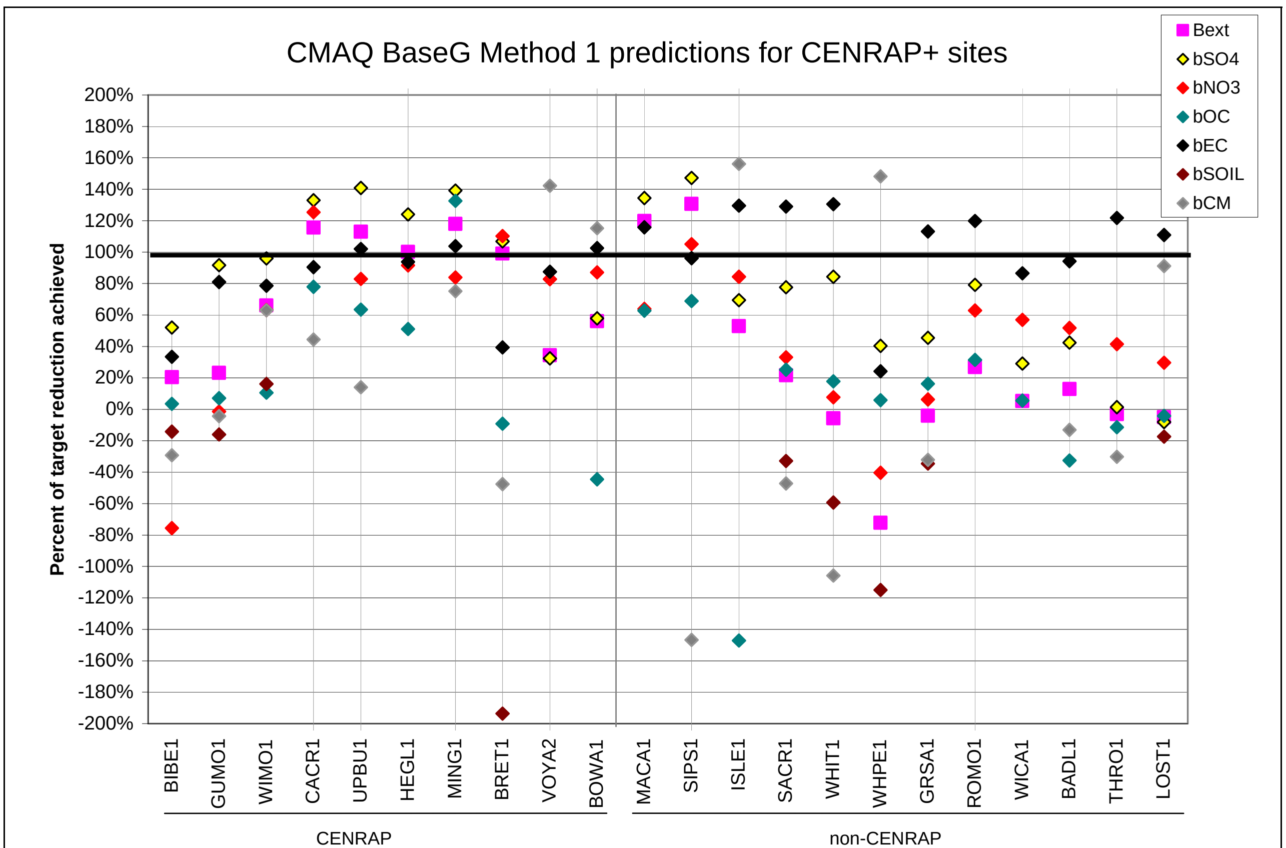

Figure 5-7. Ability of total and species specific 2018 visibility projections to achieve 2018 URP points.

5.3 Alternative 2018 Visibility Projection Software

The CENRAP 2018 visibility projections were made using software developed by the CENRAP modeling team. PM concentrations in the 36 km grid cells containing each of the Class I area IMPROVE monitoring sites were extracted using the UCR Analysis Tool. These modeling data were then ported into Excel spreadsheets that also include the filled RHR IMPROVE database available from the VIEWS website along with the EPA default Natural Conditions (EPA, 2003b). Excel macros are then used to perform the visibility projections using the EPA default procedures described in Chapter 4 and alternative procedures described in this Chapter.

EPA is developing a Modeled Attainment Test Software (MATS) program that codifies the 8-hour ozone, $PM_{2.5}$ and visibility projection procedures given in EPA's latest air quality modeling guidance (EPA, 2007a). The June 2007 release of the beta version of MATS is capable of performing 8-hour ozone and visibility projections; MATS is still under development for making $PM_{2.5}$ projections. The June 2007 beta versions of MATS was applied to the CENRAP 2002 and 2018 Base G 36 km CMAQ results and the resultant 2018 visibility projections were compared with the CENRAP values using the EPA default projection approach (see Chapter 4) at CENRAP and nearby Class I areas. The projected 2018 visibility estimates using the CENRAP and EPA MATS software are shown in Table 5-1. The biggest differences in the two 2018 visibility projections are for the Boundary Waters (BOWA). Breton Island (BRET), and Mingo (MING) Class I areas where MATS produces no 2018 visibility projections. This is because there is insufficient capture of valid IMPROVE PM measurements within the 2000-2004 five-year baseline to generate three years of annual visibility estimates that is the minimum needed to develop the Baseline Conditions following EPA's guidance (EPA, 2003a). For the CENRAP projections, data filling was used to fill out the IMPROVE measurements with sufficient data so that Baseline Conditions could be calculated at these three Class I areas. At 14 of the remaining 17 Class I areas, the CENRAP and MATS 2018 visibility projections agree exactly to within a hundredth of a deciview. At the three sites that are different (BIBE, GUMO and ISLE) the difference is 0.01 dv, which is 0.06 percent or less. These differences are likely due to round off errors in the calculations and are not significant. These results verify the consistency with the CENRAP spreadsheet based and EPA MATS software for projecting future-year visibility estimates.

Table 5-1. Comparison of CENRAP and EPA MATS 2018 visibility projections at CENRAP and nearby Class I areas.

5.4 PM Source Apportionment Modeling

The PM Source Apportionment Technology (PSAT) was used to obtain PM source apportionment by geographic regions and major source category for the CENRAP 2002 and 2018 Base E base case conditions. PSAT uses reactive tracers that operated in parallel to the CAMx host model using the same emissions, transport, chemical transformation and deposition rates as the host model to account for the contributions of user specified source regions and categories to PM concentrations throughout the modeling domain. Details on the formulation of the CAMx PSAT source apportionment can be found in the CAMx user's guidance (ENVIRON, 2006; www.camx.com).

5.4.1 Definition of CENRAP 2002 and 2018 PM Source Apportionment Modeling

PSAT calculated PM source apportionment for user defined source groups. Source groups are usually defined by specifying a source region map of geographic regions where source contributions are desired and providing source categories as input so that source group would

consist of a geographic region plus source category (e.g., on-road mobile source emissions from Oklahoma). Although other source group configurations and even individual sources may be specified. For the CENRAP PSAT application, a source region map was used that divided up the modeling domain into 30 geographic source regions as shown in Figure 5-8. The 2002 and 2018 emissions inventories were divided into six source categories. The 30 geographic source regions consisted of CENRAP and nearby states, with Texas divided into 3 regions, remainder of the western and eastern States, Gulf of Mexico, Canada and Mexico. The original intent of the CENRAP PSAT analysis was to obtain separate contributions due to on-road mobile, non-road mobile, area, natural, EGU point and non-EGU point sources. However, the CAMx emissions for the PSAT runs were based on the CMAQ pre-merged 3-D emission files. Since all point sources were contained in a single CMAQ pre-merged emissions file, then the separate source apportionment modeling of EGU and non-EGU point sources was not possible. The six source categories that were separately tracked in the PSAT PM source apportionment modeling were:

- Elevated point sources;
- Low-level point sources (i.e., point source emissions emitted into layer 1 of the model);
- On-Road Mobile Sources;
- Non-Road Mobile Sources;
- Area Sources; and
- Natural Sources.

Natural Sources included biogenic VOC and NOx emissions from the BEIS3 biogenic emissions model, emissions from wildfires and emissions from wind blown dust due to non-agriculture land use types.

PM source apportionment in PSAT is available for five families of PM tracers: (1) Sulfate; (2) Nitrate and Ammonium; (3) Secondary Organic Aerosols (SOA); (4) Primary PM; and (5) mercury. The CENRAP PSAT 2002 and 2018 applications used three of the PSAT families of tracers and did not use the SOA and mercury families. For SOA, the standard CAMx model output was used that partitions SOA into an anthropogenic (SOAA) and biogenic (SOAB) components.

The PSAT results were extracted at the CENRAP and nearby Class I areas and the contributions for the average of the worst 20 percent and best 20 percent days were processed. A PSAT Visualization Tool was developed that can be used by States, Tribes and others to generate displays of the contributions of source regions and categories to visibility impairment for the average of the worst 20 percent and best 20 percent days at each CENRAP and nearby Class I areas.

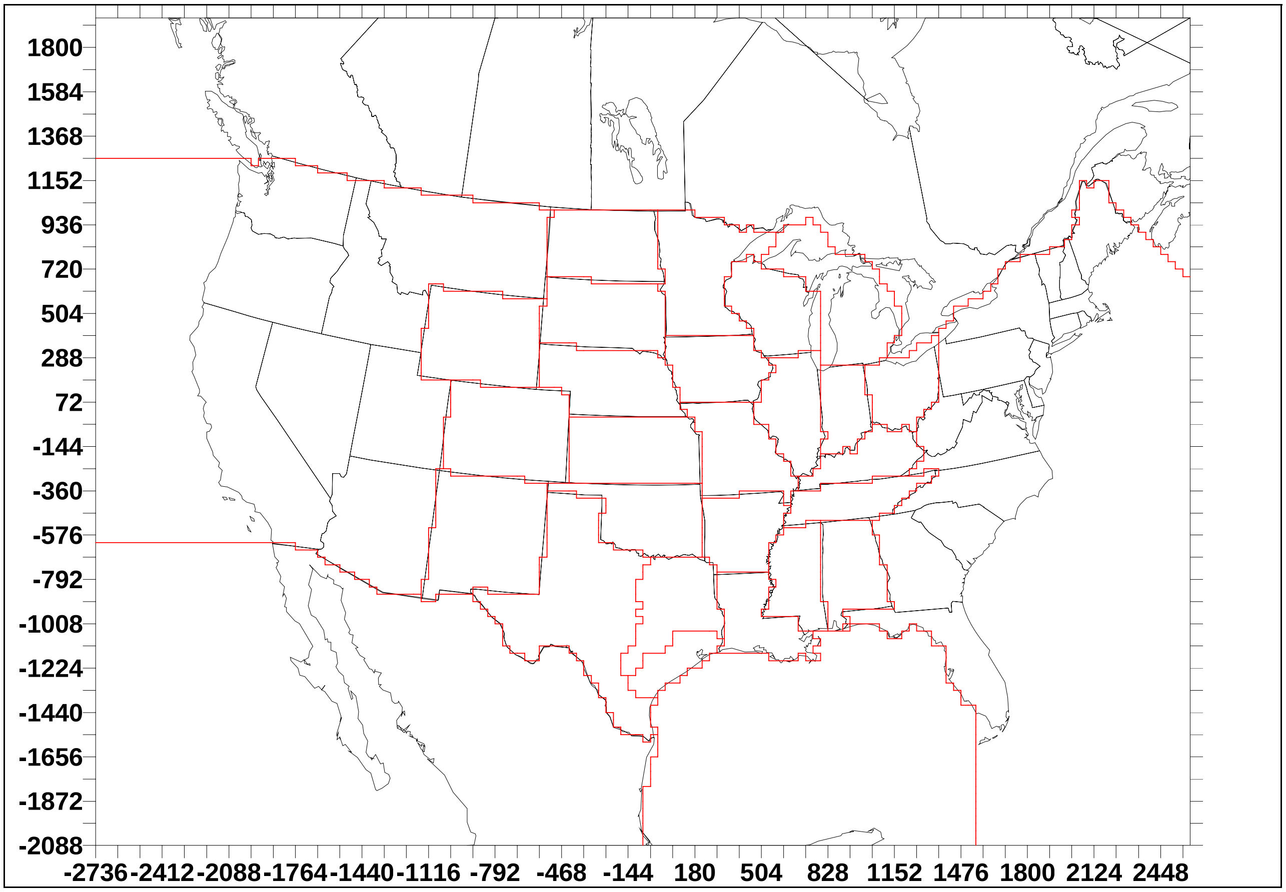

Figure 5-8. 30 source regions used in the CENRAP 2002 and 2018 CAMx PSAT PM source apportionment modeling.

5.4.2 CENRAP PSAT Visualization Tool

The PSAT Visualization Tool allows CENRAP States, Tribes and others to visualize the CENRAP 2002 and 2018 PSAT modeling results and identify which source regions, categories and PM species are contributing to visibility impairment at Class I areas for the average of the worst 20 percent and best 20 percent visibility days. The Visualization Tool is currently available on the CENRAP website (http://www.cenrap.org) under Projects. The Tool can generate bar charts of source contributions at Class I areas. It can be run in a receptor oriented mode where it identifies the contributions of PM species and source regions and categories to visibility impairment on the worst and best 20 percent days. It can also be run in a source oriented mode to examine an individual source region's (State's) contribution to visibility impairment at downwind Class I areas on the worst and best 20% days. The original IMPROVE equation is used to convert the PM species concentrations to extinction.

There are 14 air quality analysis metrics in the Tool:

> W20% Modeled Bext: The source region, source category and PM species contributions to the extinction (Bext) at a Class I area estimated by the model averaged across the worst 20 percent days in 2002.

W20% Projected Bext: The source region, source category and PM species contributions to the extinction (Bext) at a Class I area projected by the model averaged across the worst 20 percent days in the 2000-2004 Baseline.

W20% Modeled USAnthro: The source region, source category and PM species contributions to the extinction (Bext) at a Class I area for just U.S. anthropogenic emission source categories estimated by the model averaged across the worst 20 percent days in 2002.

W20% Projected USAnthro: The source region, source category and PM species contributions to the extinction (Bext) at a Class I area for just U.S. anthropogenic emission source categories projected by the model averaged across the worst 20 percent days in the 2000-2004 Baseline.

Emissions: Emissions by source region, source category and PM precursor. Precursors include SOx, NOx, primary organic aerosol (POA), primary elemental carbon (PEC) other primary fine particulate (FCRS+FPRM) and coarse mass (CCRS+CPRM). Emissions for four days have been extracted and implemented in the Tool.

Control Effectiveness: Control effectiveness is defined as the PM contribution divided by the emissions of the primary precursor. For example the SO4 contribution divided by the SO2 emissions.

Visualization Tool results are available for visibility contributions on both an absolute (Mm^{-1}) and percentage basis. When looking at contributions at a given Class I area, contributions can be examined in terms of PM species, source regions and/or source categories. Results are available for both the current year (2002 modeled or 2000-2004 projected) and future year (2018). The “2002 W20% Project Bext” metric applies the 2002 PSAT modeled source apportionment to the observed 2000-2004 Baseline extinction keeping the relative contributions of source groups to each PM species (e.g., SO4, NO3, etc.) the same averaged across the 2002 worst 20 percent days but scaling their magnitudes up or down based on the ratio of the 2000-2004 Baseline to the 2002 modeling results. Similarly, the “2018 W20% Projected” metric uses the relative contributions of the 2018 PSAT results from each source group and scales them according to the differences in the 2018 projected PM species to the 2018 modeled PM species for the average of the worst 20 percent days. The US Anthropogenic metrics just include source groups associated with U.S. man-made emissions (i.e., non-Natural source categories from states and Gulf of Mexico source regions) so excludes contributions from Canada and Mexico, Boundary Conditions, SOA from biogenic sources and the natural source category (biogenic NOx, wildfires and wind blown dust).

5.4.3 Source Contributions to Visibility Impairment at Class I Areas

Appendix E displays example contributions of PM species, source regions and source categories to visibility impairment for the worst and best 20 percent days at the CENRAP Class I areas. Some of the results from Figure E-1 for the CACR Class I area are reproduced in Figures 5-9, 5-10 and 5-11 below.

5.4.3.1 Caney Creek (CACR) Arkansas

2002 visibility impairment for the worst 20 percent days at CACR is primarily due to SO4 from elevated point sources that contributes over half (66.3 Mm^{-1}) of the total extinction of 118.8 Mm^{-1} (Figure E-1a and 5-8 left). By 2018, the total extinction at CACR for the worst 20 percent days is reduced by approximately one third (38.5 Mm^{-1}) which is primarily due to reductions in SO4 extinction from elevated point sources (from 66.3 to 37.3 Mm^{-1}) as well as reductions in visibility impairment from on-road and non-road mobile sources. Even with such large reductions in SO4 from point sources in 2018, extinction due to elevated point sources is still the highest contributor to visibility impairment on the worst 20 percent days contributing over half (41.8 Mm^{-1}) of the total extinction in 2018 of 80.3 Mm^{-1}, with area sources the next most important source category contributing 16.0 Mm^{-1} (~20%).

The geographic source apportionment for the worst 20 percent says at CACR is shown in Figures 5-10, E-1c and E-1d. Elevated point sources from the eastern source region is the largest contributor in 2002 contributing almost 18 Mm^{-1} that is reduced by over a factor of three in 2018 to approximately 5 Mm^{-1}. By 2018, Arkansas is the largest contributor to extinction at CACR for the 20 percent worst days followed by East Texas, the large Eastern U.S. region and then SOA due to biogenic sources. Figures E-1e ranks the source group contributions to extinction on the worst 20 percent days at CACR with Elevated Point Sources from East Texas being the highest contributor to total extinction, similar results are seen when examining extinction at CACR for the worst 20 percent days due to just SO4 and NO3 (Figure E-1f).

For the best 20 percent days at CACR (Figures 5-11, E-1g-j), SO4 is still a major contributor but no where near as dominate as seen for the worst 20 percent days, but elevated point is still the largest contributing source category Local contributions from within Arkansas contribute the most to the average of extinction across the best 20 percent days at CACR.

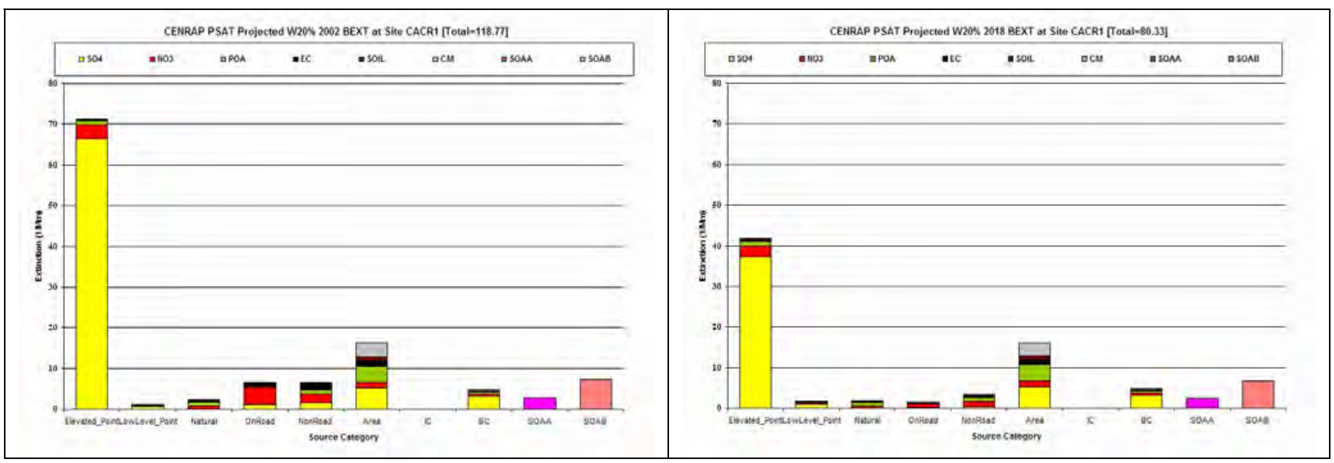

Figure 5-9. PSAT source category by PM species contributions to the average 2000-2004 Baseline and 2018 projected extinction (Mm^{-1}) for the worst 20 percent visibility days at Caney Creek (CACR), Arkansas.

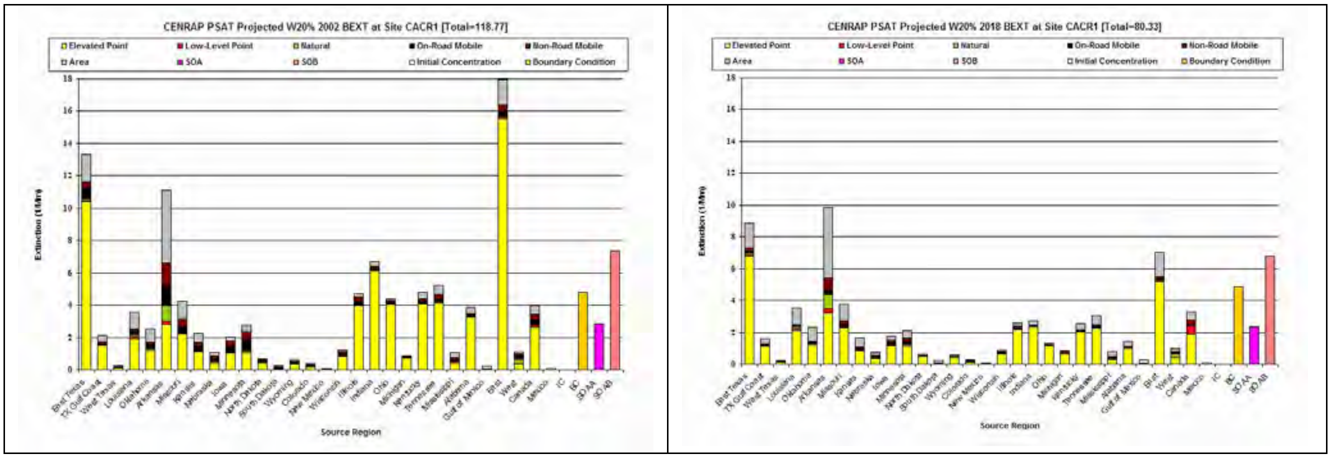

Figure 5-10. PSAT source region by source category contributions to the average 2000-2004 Baseline and 2018 projected extinction (Mm^{-1}) for the worst 20 percent visibility days at Caney Creek (CACR), Arkansas.

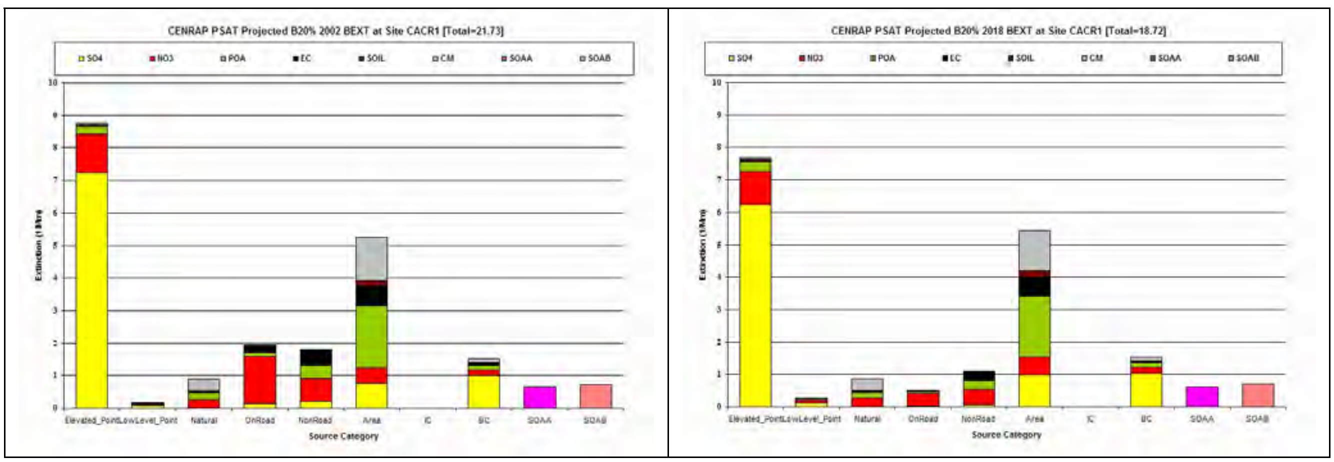

Figure 5-11. PSAT source category by PM species contributions to the average 2000-2004 Baseline and 2018 projected extinction (Mm^{-1}) for the best 20 percent visibility days at Caney Creek (CACR), Arkansas.

5.4.3.2 Upper Buffalo (UPBU) Arkansas

The contributions to extinction on the worst 20 percent days at UPBU (Figure E-2) is similar to CACR only with less contributions from East Texas and more from Missouri, Illinois and Indiana. By 2018, the top five highest contributing source groups to the average extinction on the worst 20 percent days are as follows: Arkansas Elevated Point; SOA from biogenics; Boundary Conditions, East Elevated Points, and Illinois Elevated Points (Figure E-2e). On the best 20 percent days at UPBU visibility impairment is primarily due to Arkansas and adjacent states Oklahoma, Missouri, and Kansas).

5.4.3.3 Breton Island (BRET) Missouri

Visibility impairment for the worst 20 percent days at Breton Island is primarily (69%) due to elevated point sources that contribute 77.7 Mm^{-1} out of a total of 122.2 Mm^{-1} (Figure E-3a). Although the contribution of elevated point sources is reduced substantially by 2018, they still contribute over half of the total extinction (101.1 Mm^{-1}) on the worst 20 percent days at BRET (Figure E-3b). The top five contributing source groups to 2018 visibility impairment at BRET for the worst 20 percent days are: Louisiana Elevated Point Sources; Boundary Conditions; East Elevated Point Sources; Gulf of Mexico Area Sources and Louisiana Area Sources. Gulf of Mexico Area sources includes off shore shipping and oil and gas development emissions; note that for the PSAT simulation the off-shore marine shipping emissions were double counted which was corrected in the Base G emission scenarios used in the 2018 visibility projections discussed in Chapter 4.

5.4.3.4 Boundary Waters (BOWA) Minnesota

As seen for the other Class I areas, elevated point sources contribute the largest amount (47%) to visibility impairment at BOWA for the worst 20 percent days in 2002 (Figure E-4a). However, unlike many of the other Class I areas, there is little reductions (~10%) in the elevated point source contributions going from 2002 (29.0 Mm^{-1}) to 2018 (26.2 Mm^{-1}) (Figures E-4a and E-4b). This is because there is a slight increase in the contributions of elevated point sources in Minnesota from 2002 to 2018 (Figures E-4c and E-4d) that is the highest contributing source group (Figure E-4e). Note that the 2018 emission scenario includes growth and CAIR controls but no BART controls. For the best 20 percent days, the largest contributing source group by far is Boundary Conditions (i.e., global transport) followed by Minnesota and Canada (Figures E-4g-j).

5.4.3.5 Voyageurs (VOYA) Minnesota

Results for VOYA are similar to BOWA with Minnesota, Canada and Boundary Conditions contributing the most to visibility impairment on the worst and best 20 percent days (Figure E-5).

5.4.3.6 Hercules Glade (HEGL) Missouri

Elevated point sources contribute over half to the total extinction for the worst 20 percent days at HEGL in 2002 (Figures E-6a and E-6b). Going from 2002 to 2018 the contributions due to elevated point sources, on-road mobile and non-road mobile are reduced substantially, but the contributions due to the other sources remain unchanged. The largest source group contributing to visibility impairment on the worst 20 percents days is area sources from Missouri in both 2002 and 2018 (Figures E-6c and E-6d). Since area emissions are not reduced much between 2002 and 2018 and Missouri elevated point sources are mostly unchanged because the IPM model assumed Missouri CAIR sources would buy credits, then the Missouri contributions is only reduced a little going from 2002 to 2018 (from ~18 Mm-1 to ~16 Mm-1). However, the contributions due to the Eastern U.S., Illinois and Indiana are reduced substantially. Missouri is by far the largest contribution to visibility impairment at UPBU on the best 20 percent days as

well with area sources from Missouri being the largest source category (Figures E-6h through E-6j).

5.4.3.7 Mingo (MING) Missouri

The substantial improvements in visibility impairment at MING for the worst 20 percent days from 2002 (141 Mm^{-1}) to 2018 (96 Mm^{-1}) is primarily due to reductions in SO4 from non-Missouri elevated point sources (Figures E-7a through E-7d). Even so, with the exception of the top contributing Missouri area sources the largest contributing source groups to 2018 visibility impairment for the worst 20 percent days are still elevated point sources from several CAIR states (Illinois, Indiana, Missouri, East; Figure E-7e). Missouri is the largest contributor to visibility on the best 20 percent days followed by Boundary Conditions and Illinois (Figure E-7i-j).

5.4.3.8 Wichita Mountains (WIMO) Oklahoma

Elevated point sources are the largest contributors to visibility impairment on the worst 20 percent days at WIMO in both 2002 and 2018 (Figures E-8a and E-8b). East Texas followed closely by Oklahoma are the largest contributing source regions in 2002, but by 2018 the reverse is true (Figures E-8c and E-8d). By 2018 the largest contributing source group to visibility impairment on the worst 20 percent days at WIMO is global transport (i.e., boundary conditions) followed by Oklahoma Area Sources and East Texas Elevated Point sources (Figure E-8e). Oklahoma Area Sources is the largest contributor to visibility impairment on the best 20 percent days at WIMO (Figures E-8g-j).

5.4.3.9 Big Bend (BIBE) Texas

Elevated point sources (~17 Mm^{-1}) followed by Boundary Conditions (~12 $Mm^{-}1$) are the largest contributions to total extinction (46 Mm^{-1}) on the worst 20 percent days at BIBE in 2002 (Figure E-9a). In 2018 there is very little (~2 Mm^{-1}) reduction in the contributions of elevated point sources and no reductions in global transport resulting in little reductions (~7%) in visibility impairment on the worst 20 percent days from 2002 (46 Mm^{-1}) to 2018 (43 Mm^{-1}). This is due to the extremely large contributions of emissions from Mexico in both 2002 (Figure E-9c) and 2018 (Figure E-9d). In fact, the four highest contributing source groups to visibility impairment at BIBE for the worst 20 percent days are assumed to be unchanged from 2002 to 2018: Boundary Conditions, Mexico Elevated Points, West Texas Natural and Mexico Natural (Figure E-9e). For the best 20 percent days at BIBE, West Texas, Mexico and Boundary Conditions are the highest three contributors to visibility impairment (Figures E-9g-j).

5.4.3.10 Guadalupe Mountains (GUMO) Texas

The large contribution of CM to visibility impairment at GUMO is clearly evident in the source apportionment modeling results (Figures E-10a-b). These sources are about evenly divided in the modeling between natural sources and area sources. Since these source categories are not reduced in the future year then there is little reduction in extinction from 2002 to 2018 (50 to 45

Mm^{-1}) and what reductions there are come from Elevated Point Sources. Sources in West Texas, Mexico, Boundary Conditions and New Mexico are the largest contributing source regions for both the worst 20 percent days (Figure E-10c-e) and best 20 percent days (Figures E-10g-j).

5.5 Alternative Visibility Projection Procedures

In this section we analyze several alternative visibility projection procedures from the EPA's default approach (EPA, 2007a) used in Chapter 4.

5.5.1 Treatment of Coarse Mass and Soil

As noted previously, much of the coarse mass (CM) and, to a lesser extent, Soil measured at the IMPROVE monitor is likely due to local wind blown dust that is natural in origin and not captured by the model. Consequently, even using the modeling results in a relative sense with the RRFs may not be appropriate for projecting CM and Soil. If CM and Soil are in fact local impacts due to wind blown dust from natural lands, then it would be appropriate to assume they are natural and remain unchanged from the 2000-2004 Baseline to 2018. This is probably certainly appropriate for CM because CM is primarily due to fugitive dust and it has a very short transport distance that is subgrid-scale to the model. In fact the model evaluation discussed in Chapter 3 and Appendix C clearly shows a large underprediction bias for CM that is likely due to local fugitive dust impacts at the IMPROVE monitor. For Soil this is less clear as fine particles can be transported over longer distances and is produced by anthropogenic sources, such as combustion and road dust, as well as natural sources. We initially performed two CM and Soil sensitivity tests, the first assumed CM was all natural so remains unchanged from the 2000-2004 Baseline to 2018 (i.e., set the RRF for CM equal to 1.0). The second sensitivity test assumed both CM and Soil were natural so set RRFs for both of them to 1.0. A comment from an FLM noted that we know some of the Soil is likely anthropogenic in origin. So it was suggested to subtract the 2002 base case modeled Soil from the observed values for the 2002 worst 20 percent days and assume that the remainder (if any) was natural so hold the rest of the Soil constant in 2018 and add to the 2018 modeled Soil values.

The results of the CM and Soil visibility projection sensitivity analysis are shown in the DotPlot in Figure 5-12. The CM and Soil visibility projection sensitivity analysis has little effect on the 2018 visibility projections at the CENRAP Class I areas. Even GUMO, which has a large CM and Soil component, shows very little sensitivity. This is probably because the CM at GUMO is likely dominated by wind blown dust that was assumed constant from 2002 to 2018 so the RRF calculated using the default EPA method is near 1.0 anyway. Some larger sensitivity is seen at several WRAP Class I areas. It is encouraging that CENRAP 2018 visibility projections are not sensitive to the CM and Soil components of the modeling which are highly uncertain.

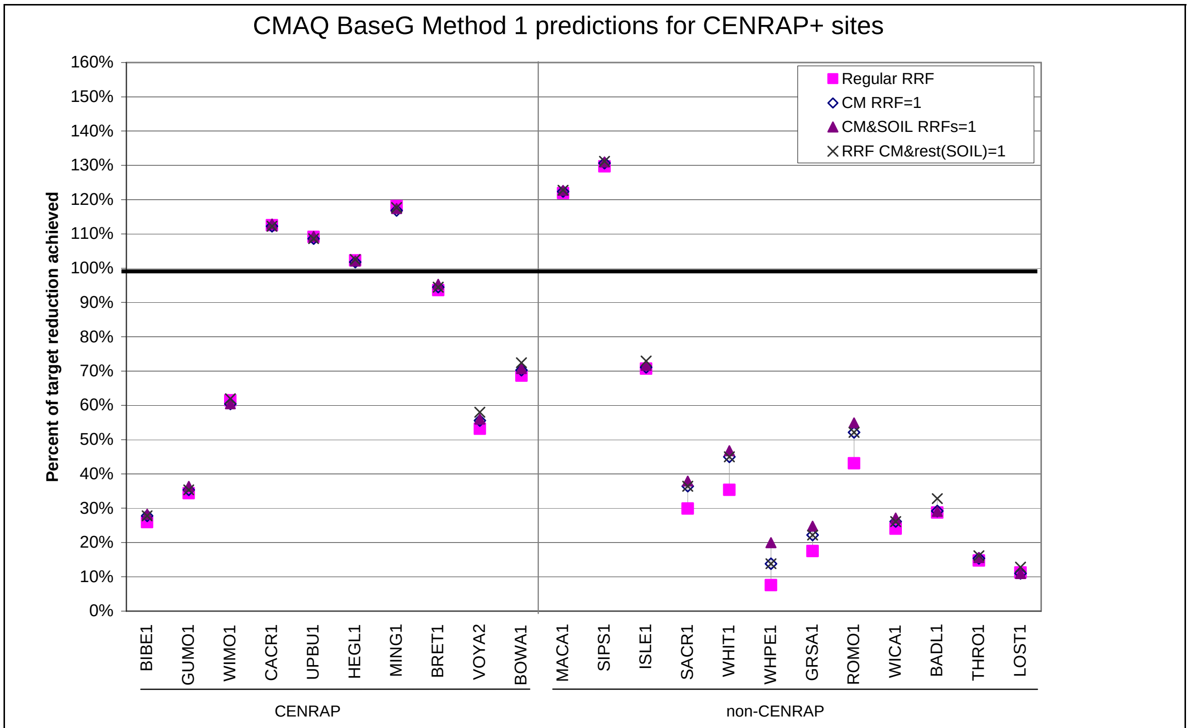

Figure 5-12. Sensitivity of 2018 visibility projections to various methods that assume all CM, all CM and Soil and all CM and part of the Soil is natural.

5.6 Alternative Model

The CAMx model was also run for a 2002 and 2018 base case scenarios with earlier versions of the CENRAP emissions (Base E modified to eliminate double counting of some area fire emissions) than the final CMAQ 2002 Base G modeling. The CAMx 2002 and 2018 output was processed the same way that the CMAQ results were to generate 2018 visibility projections at the CENRAP and nearby Class I areas that were compared with the 2018 URP point. Figure 5-13 summarizes the CAMx 2018 visibility projections using the new IMPROVE algorithm (NIA) in a DotPlot and compares them with the CMAQ 2018 Base G results (from Figure 5-12). The CMAQ and CAMx 2018 visibility projections are remarkably similar. The four Arkansas and Missouri Class I areas are projected to achieve the 2018 URP point by almost the exact same amount by the two models. The two Texas Class I areas are projected to come up short of achieving the 2018 URP point by the same amount by the two models. The largest differences are seen at BRET, and to a lesser extent BOWA and VOYA. At BRET the CAMx 2018 visibility projections are much less optimistic (< 80%) in achieving the 2018 URP point than CMAQ (> 90%). And CMAQ is slightly less optimistic than CAMx in achieving the 2018 URP point for the two northern Minnesota Class I areas. The reasons for these differences are unclear but could be partially due to the emissions updates in the final CMAQ Base G run that included eliminating the double counting of off-shore marine emissions in the Gulf of Mexico that was present in the CAMx simulation, which makes it more difficult to get visibility improvements at BRET since it is influenced by sources in the Gulf. Corrections to stack parameters for Canadian point sources were also made for the final Base G. The general close agreement of the CAMx 2018 visibility projections to the final CMAQ values is encouraging and good QA check.

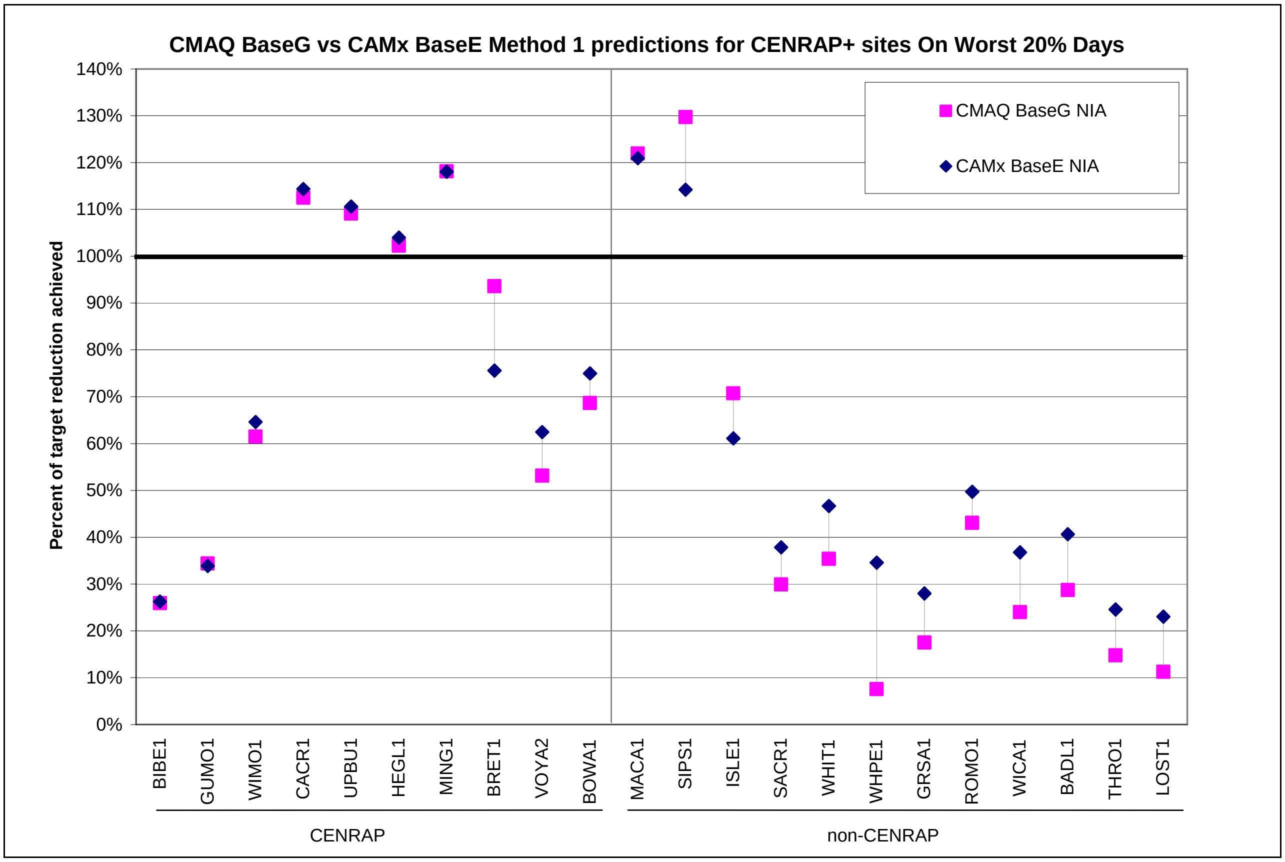

Figure 5-13. Comparison of CAMx 2018 visibility projections with 2018 URP points for CENRAP and nearby Class I areas.

5.7 Effects of International Transport on 2018 Visibility Projections

As seen in the PM source apportionment modeling discussed in Section 5.4, there is significant contributions of international sources to visibility impairment at many CENRAP Class I areas for the worst 20 percent days. With the exception of Canada, where we used a year 2000 inventory for the 2002 base case modeling and a 2020 inventory for the 2018 inventory, international sources were assumed to be constant between 2002 and 2018. Thus, Class I areas that are heavily impacted by contributions of international transport will have a difficult time achieving the 2018 URP point since international sources are assumed to remain constant. The CAMx PSAT runs discussed previously provide a framework for quantitatively assessing the contributions of international transport to the visibility projections and whether reasonable progress toward natural conditions is being achieved in the 2018 modeling.

There are several source regions (Figure 5-8) and source categories in the PSAT modeling that include international sources:

- Mexico Anthropogenic Sources (assumed all international);
- Canada Anthropogenic Sources (assumed all international);
- Gulf of Mexico (assumed all U.S. sources);
- Pacific and Atlanta Ocean (assumed all U.S. sources); and
- Boundary Conditions (assumed half international and half natural sources).

Although it can be argued that Mexico and Canada are not truly international due to the presence of numerous U.S. corporations in Mexico along with free trade among the two countries, states and federal government have no jurisdiction to regulate industry in these two countries so they are considered international in these calculations. The Gulf of Mexico includes off-shore oil and gas production facilities, support vessels and aircraft and off-shore marine shipping. Given that emissions from the oil and gas production can be regulated by the U.S., then the Gulf of Mexico is not considered an international source. Emissions from off-shore shipping in the Pacific and Atlantic Oceans are also currently not regulated by the U.S. government. However, there are current efforts to apply some regulations to these emissions so for these calculations they were not assumed to be international sources. Finally, the Boundary Conditions (BCs) for the CENRAP modeling were generated from a 2002 simulation of the GEOS-CHEM global chemistry model and held constant in 2018. These BCs would include contributions from international sources as well as natural sources, so need to be split. For the sensitivity calculations discussed below we assumed that the BCs were half due to natural and half due to international sources. This results in international sources being defined as follows:

International Contribution = Mexico Anthro + Canada Anthro + ½ BCs

Two methods were examined to see what the effects of international sources on 2018 visibility projections and a Class I areas ability to achieve the 2018 URP point:

<u>Elimination of International Contributions to 2018 Visibility Projections</u>: In this method the contribution of international emissions is taken out of the 2018 visibility projections and examined to see whether the new visibility projection achieves the URP point. If so, then international sources are hindering a Class I area in achieving the 2018 URP point, which suggests that the 2018 URP point is not a reasonable value for an RPG.

<u>Visibility Projections and Glidepaths Based on Controllable Visibility Impairment</u>: The second method would look at the visibility projections for just the U.S. controllable portion of the visibility impairment. The glidepath end point in 2064 would be to eliminate the U.S. man-made contributions to visibility impairment on the worst 20 percent days.

Note that this analysis is performed solely for providing states and others additional information on which Class I areas the modeling suggest are unduly influenced by International Transport.

5.7.1 Elimination of International Contributions to 2018 Visibility Projections

This method was also discussed in a recent technical brief prepared by the Electric Power Research Institute (EPRI), only in EPRI's analysis they used results from a global chemistry model and VISTAS CMAQ runs with no global anthropogenic emissions (EPRI, 2007). Thus, before discussing our results of this analysis using PSAT, we discuss EPRI's analysis.

5.7.1.1 EPRI's Analysis of Effects of International Contributions

EPRI funded Harvard University to perform annual simulations of the GEOS-Chem global chemistry model (http://www-as.harvard.edu/chemistry/trop/geos/) for annual simulations with and without non-U.S. anthropogenic emissions to determine the contributions of international transport to PM and visibility. The EPRI Harvard GEOS-Chem simulations were performed for 2001. Figure 5-14 and 5-15 compare the annual average ammonium sulfate, ammonium nitrate organic mass carbon (OMC, also called OCM) and elemental carbon (EC) due to the GEOS-Chem global modeling and the CAMx PSAT source apportionment modeling. The similarity of the results for ammonium sulfate is remarkable (Figure 5-14). Both methods estimate that the annual average ammonium sulfate contribution due to international sources ranges from 0.4 to 1.0 $\mu g/m^3$ across the Class I areas. There is less agreement between the two methods for ammonium nitrate due in part to a CAMx overestimation issue that is likely due in part to how ammonia emissions were classified as being anthropogenic or not in the no U.S. anthropogenic emissions simulations (Figure 5-15). Better agreement is seen between the two methods international contributions of OMC and EC, although CAMx estimates higher contributions than GEOS-Chem.

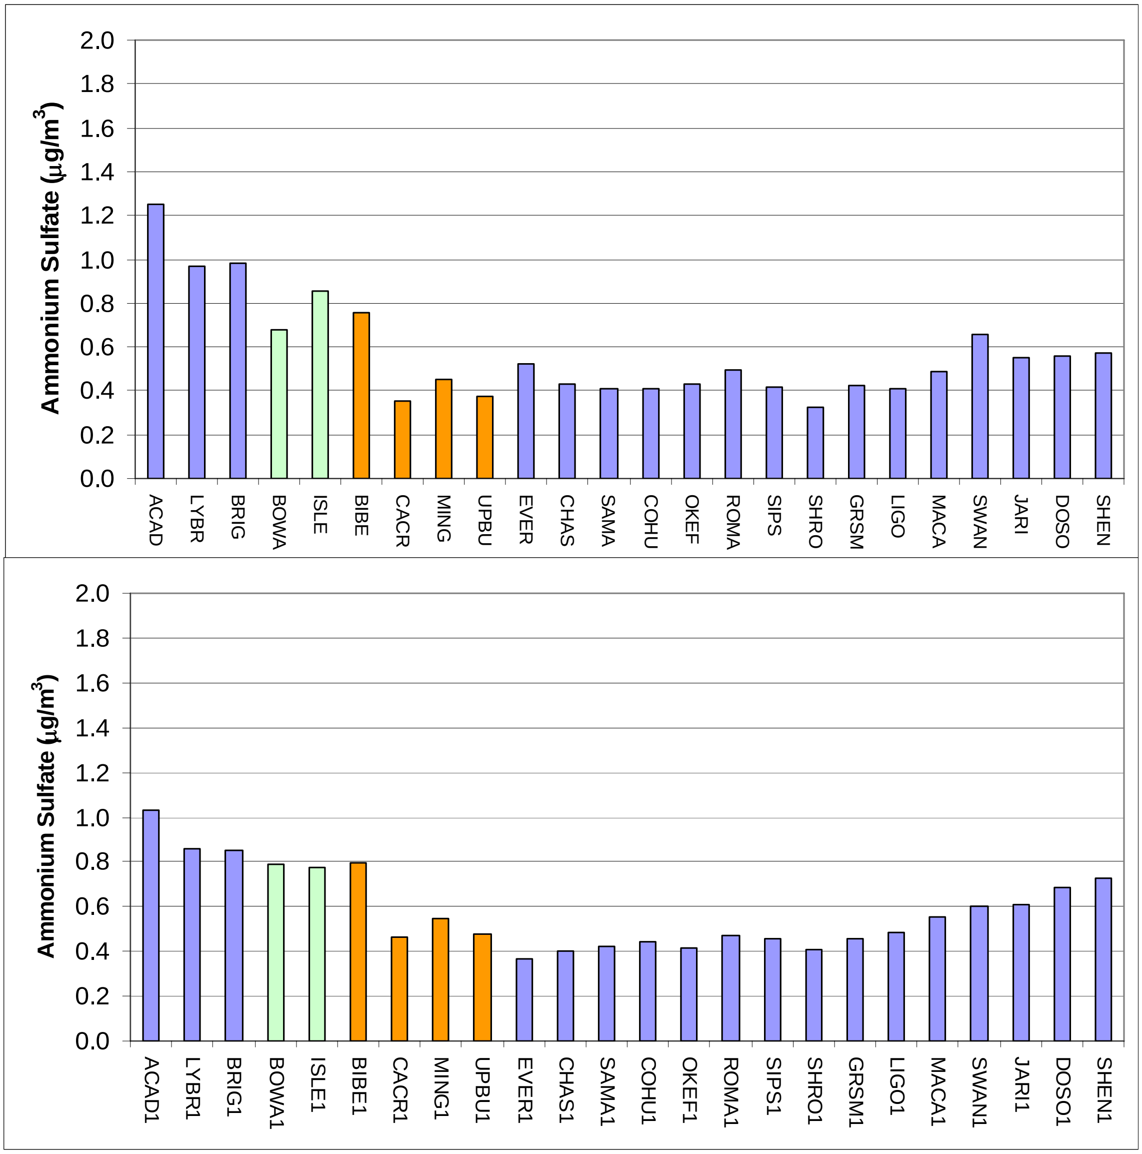

Figure 5-14. Comparison of EPRI Harvard GEOS-Chem global chemistry (top) and CENRAP PSAT (bottom) international source contributions to ammonium sulfate at Class I areas.

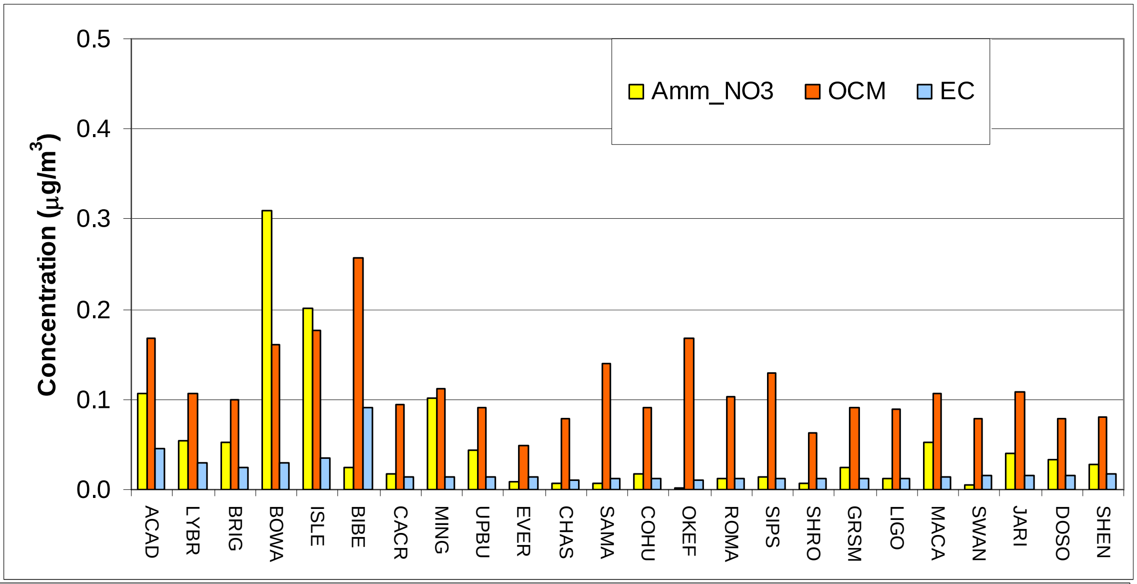

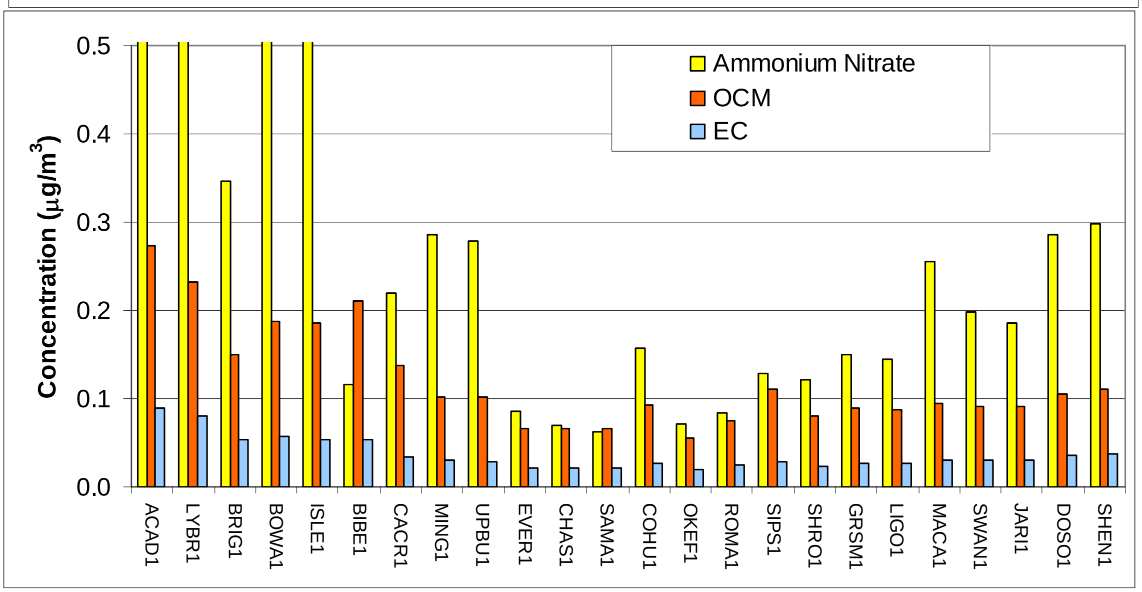

Figure 5-15. Comparison of EPRI Harvard GEOS-Chem global chemistry (top) and CENRAP PSAT (bottom) international source contributions to ammonium nitrate, organic carbon mass (OCM or OMC) and elemental carbon (EC) at Class I areas.

The EPRI technical brief used the VISTAS CMAQ runs to adjust the modeled 2018 visibility projections to eliminate the effect of international transport and compared them to the 2018 URP point. For the Boundary Waters, Voyageurs, Isle Royal and Seney Class I areas the standard 2018 visibility projections did not achieve the 2018 URP point. However, when the effect of transboundary pollutions was removed the 2018 URP point was essentially achieved or more than achieved at all four Class I areas.

5.7.1.2 CENRAP Results From Elimination International Transport

Because the elimination of the international sources from the 2018 visibility projections results in a portion of the total light extinction, then these comparisons with the 2018 URP points were done using extinction glidepaths and projections rather than deciview. In Section 5.2.1 we demonstrated that the level of achieving the 2018 URP point was almost identical at CENRAP Class I areas whether the linear deciview or curved extinction glidepaths were used. The PSAT source apportionment was used to determine the contribution to the projected extinction in 2018 due to international sources. As noted above, international sources were assumed to be due to anthropogenic emissions in Mexico and Canada and half of the Boundary Conditions.

Figure 5-16 shows the standard CAMx extinction glidepaths and 2018 visibility projections and the 2018 visibility projections when the contributions of international sources is eliminated. CACR, which achieved the 2018 URP point by 104%, achieves it by even more when international sources are eliminated (117%). UPBU that barely achieved the 2018 URP point by 102% achieves it by 116% without international emissions.

BRET comes up short of achieving the 2018 URP point when international emission are included (76%) as well as when they are eliminated (92%), although it is much closer (recall contributions of Gulf of Mexico to visibility impairment at BRET that is assumed in this analysis to be of U.S. origin). Eliminating international transport emissions makes of difference of meeting the 2018 URP point without them (120%) to not meeting it with them (64%) at BOWA. Similarly at VOYA the standard 2018 visibility projections do not achieve the 2018 URP point (54%), whereas it is achieved by a far margin when international sources are eliminated (132%).

HEGL comes up short achieving the 2018 URP point when international sources are included (95%), but achieves it when they are eliminated (107%). Recall the standard CAMx deciview visibility projections barely achieved the URP point even when international emissions are included (Figure 5-13). MING achieves the 2018 URP point with (106%) and without (116%) international sources. WIMO does not achieve the 2018 URP point when international contributions are eliminated.

International sources have by far the largest effect at BIBE. Whereas the standard 2018 visibility projections only achieved 27% of the reductions needed to achieve the 2018 URP point, elimination of the international source contributions achieves 172% of the reduction needed. GUMO comes up short in achieving the 2018 URP point when international sources are included (31%), but achieves it when they are not (107%).

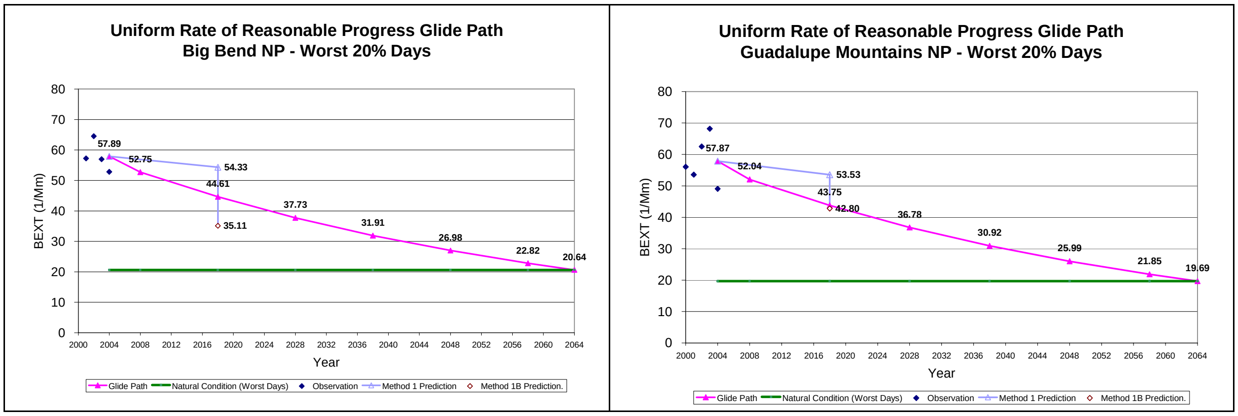

Figure 5-16. Elimination of international sources from 2018 visibility projections and comparison with 2018 URP point at CENRAP Class I areas.

5.7.2 Glidepaths Based on Controllable Extinction

Another alternative glidepath that was examined using the CAMx PSAT source apportionment results was based on the U.S. anthropogenic emissions contributions to visibility impairment on the worst 20 percent days at the CENRAP Class I areas. The RHR strives to achieve "natural visibility conditions" by 2064 and defines natural conditions as conditions that would exist "in the absence of human caused impairment". As shown above, anthropogenic emissions from international sources contribute significantly to visibility impairment at many of the CENRAP Class I areas making the RHR objective not practical if contributions from such sources are not reduced. Given that states and EPA have no jurisdiction over international sources, then we can not assume they will be controlled and have therefore held most of them constant at 2002 levels. For such Class I areas with high contributions from international sources, the comparison with the 2018 URP point is not very meaningful since the 2018 URP assumes such sources will be reduced. A more meaningful comparison would be to focus on the U.S. man-made contributions to visibility impairment at the Class I areas and develop a URP glidepath and 2018 URP point that is aimed at eliminating the U.S. anthropogenic emissions contributions to visibility impairment at Class I areas for the worst 20 percent days in 2064.

The CAMx 2002 base case PSAT PM source apportionment results were processed to identify the portion of the 2000-2004 Baseline extinction that was due to U.S. anthropogenic emissions (i.e., man-made sources). The contributions of source groups that included on-road mobile, non-road mobile, elevated point sources, low-level point sources and area sources from the PSAT source regions covering the U.S. states and Gulf of Mexico (Figure 5-8) were assumed to make up the U.S. anthropogenic contributions (i.e., excluding the Natural source category, all sources from the Mexico and Canada source regions and boundary conditions). Note that off-shore marine emissions in the Pacific and Atlantic Oceans and Gulf of Mexico were included in the U.S. anthropogenic emissions definition because they were in source regions associated with states or the Gulf of Mexico. As off-shore marine emissions may not be controllable by U.S. agencies and they were assumed to remain unchanged going from 2002 to 2018, then the 2018 visibility projections for the U.S. anthropogenic component are overstated.

The 2064 objective for the U.S. anthropogenic emissions glidepath would be no contributions on the worst 20 percent days. This does not mean the 2064 U.S. anthropogenic extinction objective

is zero, rather the U.S. anthropogenic plus natural background is less than the Natural Conditions for the worst 20 percent days. The PSAT results were used to define the natural background contributions on the current worst 20 percent days which was subtracted from the EPA default Natural Conditions to obtain the 2064 objective for the U.S. anthropogenic emissions contributions. Here the PSAT derived natural background was defined as the sum of the contributions from the Natural source category, secondary organic aerosol from biogenic sources (SOAB) and half of the boundary conditions. For example, Figure 5-17 top left displays the US anthropogenic emissions glidepath for CACR. The PSAT natural sources contribution (=Natural Source Category + SOAB + ½ BC) is approximately 13 Mm^{-1} so that is subtracted from the 2064 Natural Background (~32 Mm^{-1}, see figure 5-16) to obtain a 2064 end point of ~19 Mm^{-1} for the glidepath. The 2002 PSAT results applied to the 2000-2004 Baseline extinction estimates that 111 Mm^{-1} of the extinction is due to U.S. anthropogenic emissions which form the starting point for the glidepath. The curvature in the US anthropogenic glidepath is introduced the same way as for the extinction based glidepath to account for the logarithmic relationship between extinction and deciview.

Figure 5-17 displays the U.S. anthropogenic emissions extinction glidepaths and comparison with the 2018 visibility projections for extinction due to U.S. anthropogenic emissions on the worst 20 percent days. As seen by the standard linear deciview glidepaths discussed in Chapter 4, the U.S. anthropogenic emissions 2018 URP point is achieved by a wide margin at the four Class I areas in Arkansas and Missouri (CACR, UPBU, HRGL and MING). BRET that achieved 94% of the 2018 URP point obtains similar results using the U.S. anthropogenic emissions glidepath achieving 96% of the 2018 URP point. As discussed above, the inclusion of the off-shore marine emissions in the U.S. anthropogenic emissions will greatly affect the BRET Class I area so that actual reduction in U.S. anthropogenic emissions extinction would be greater and may even achieve the 2018 URP point if off-shore marine vessels were classified as not being part of the U.S..

The BOWA and VOYA northern Minnesota Class I areas achieved, respectively, 69% and 53% of the 2018 URP point using the standard EPA default deciview glidepaths and projection techniques (Figure 4-4). Using the U.S. anthropogenic glidepaths BOWA and VOYA achieve 92% and 86% of the 2018 point, respectively (Figure 5-17). WIMO that came up approximately 40% short of achieving the 2018 URP point using the deciview glidepath comes up under 20% short using the U.S. anthropogenic emissions glidepath.

The two Texas Class I areas also come up short in achieving the 2018 URP point using the U.S. anthropogenic emissions glidepaths, but not as short as when the linear deciview glidepaths are used. BIBE increases from 26% to 67% and GUMO increases from 34% to 49%. One reason these two Class I areas fail to achieve the 2018 point for U.S. anthropogenic emissions is because of the high contributions of Soil and CM and little change in precursor emissions of these species between 2002 and 2018.

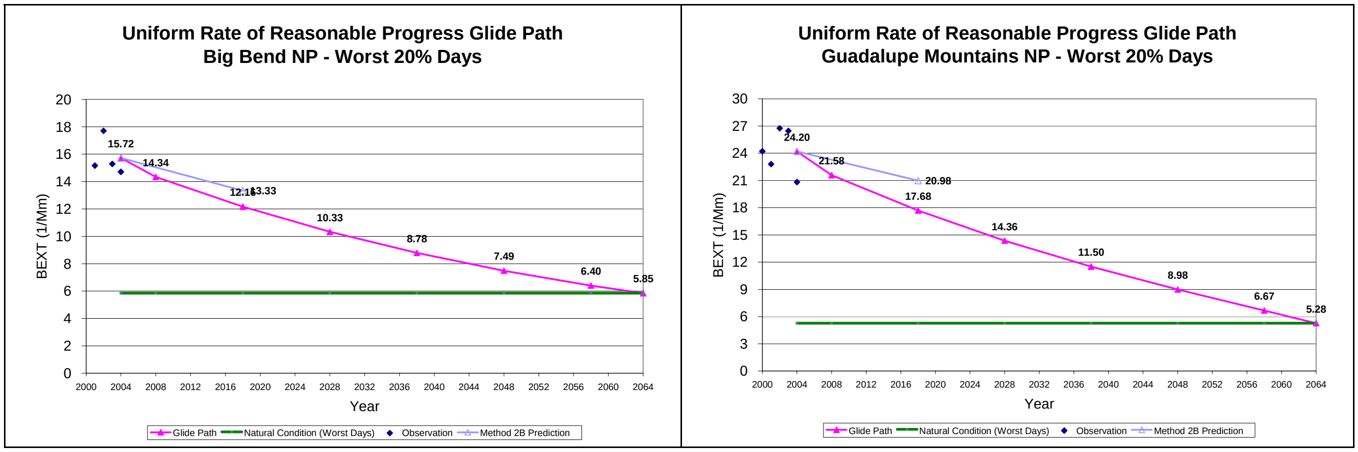

Figure 5-17. Glidepaths and 2018 visibility projections based on visibility due to U.S. anthropogenic emissions at CENRAP Class I areas.

5.8 Use of Original IMPROVE Equation

2018 visibility projections were also made using the CENRAP Typ02g and Base18g CMAQ modeling results and the original (old) IMPROVE equation. Figure 5-18 displays a DotPlot that compares the 2018 Base G visibility projections using the new IMPROVE algorithm (NIA) and the original IMPROVE algorithm (OIA). In general the new IMPROVE equation results in more optimistic 2018 visibility projections than the original IMPROVE equation. For the Texas and WRAP Class I areas, the 2018 visibility projections are nearly identical using the two IMPROVE equations. For the four Class I areas in Arkansas and Missouri the 2018 visibility projections using the new IMPROVE equation are from 7 to 21 percentage points more optimistic than the original IMPROVE equation. In the case of UPBU, HEGL and MING the 2018 visibility projections go from not achieving to achieving the 29018 URP point when switching from the old to new IMPROVE equation.

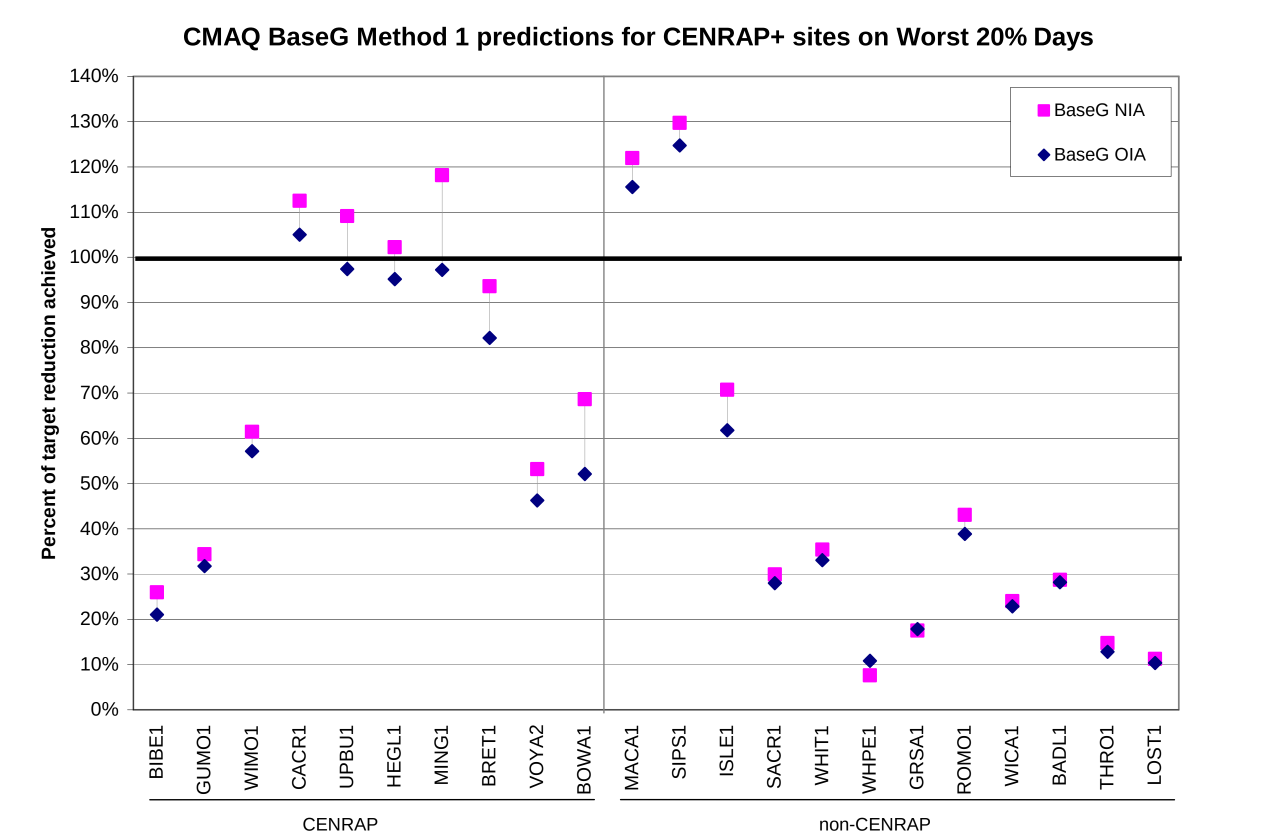

Figure 5-18. Comparison of 2018 Base G visibility projections using the New (NIA) and Old (OIA) IMPROVE algorithms expressed as a percentage of achieving the 2018 URP point visibility improvements.

5.9 Visibility Trends

Figure 5-19 displays trends in visibility impairment at the CENRAP Class I areas using the period of record of measurements at the associated IMPROVE monitor and the new IMPROVE equation. These trends include trends for the worst 20 percent days, the best 20 percent days and all IMPROVE sampled days during a year. The EPA guidance procedures were used to construct the worst and best 20 percent days that includes a minimum data capture requirement (EPA, 2003a), whereas no such minimum data capture was applied when looking at the "annual average" of all IMPROVE sampled days trends. So care must be taken when analyzing trends for the all sampled IMPROVE days trends as there could be large missing periods with high or low extinction that are not being account for. The WRAP Technical Support System (TSS) website was used to calculate the visibility trends at the CENRAP Class I areas that includes IMPROVE data from start of recording through 2004 and includes no data filling (see: http://vista.cira.colostate.edu/TSS/Default.aspx) .

Trends in visibility at CACR has three years of data (2002-2004) for the worst and best 20 percent days and fives years for the IMPROVE sampled days trends. Although it is hard to come to any conclusions regarding trends with just three years of data, there does seem to be a general downward trend, that is also supported by the five year trend in the IMPROVE sampled days.

A much longer trend plot is available for UPBU that includes 12 years of data for the worst and best 20 percent days (Figure 5-19b). Although there is a lot of a year-to-year variation in the visibility trends with cleaner years occurring in 1997, 2001 and 2004, there does appear to be a slight trend toward improved visibility at UPBU.

There is insufficient data to calculate the worst or best 20 percent days visibility for any year at the BRET Class I area so only the IMPROVE sampled days trends are presented (Figure 5-19c). The trends at BRET are inconclusive and given the large amounts of missing data at this site it is difficult to interpret the results.

There is also a lot of missing years in the worst and best 20 percent days for the BOWA Class I area making it difficult to interpret (Figure 5-19d). But visibility appears to be more impaired in the early 1990s than in more current years so improvements have been seen. VOYA has five years of valid data and shows worsening visibility for 2000-2003, and then improved visibility in 2004. It is unclear whether the 2004 improved visibility is a trend or just due to variations in meteorology so no conclusions can be drawn.

Although a downward trend in visibility impairment appears to be occurring at the two Missouri Class I areas (Figure 5-19f-g), given that there are only three years available for HEGL and lots of missing data for MING these trends are inconclusive.

Three years (2002-2004) of visibility trends for the worst and best 20 percent days are available for WIMO (Figure 5-19h). The most impaired year from the three years for the worst 20 percent days is the most recent (2004). Again, the time period is too short to draw any conclusions on trends in visibility at WIMO.

The two Texas Class I areas have a relatively long period of record. There is a lot of year-to-year variability in the visibility measurements that make interpreting the trends difficult. 1998 appears to be an anomalously high visibility impairment year at BIBE and due to the much higher OMC extinction indicates that the year was likely impacted by smoke from fires. GUMO has lots of year to year variability in CM and Soil which are likely due to occurrences of impacts due to wind blown dust. Even taking Soil and CM out of the interpretation it is difficult to interpret ay trend in visibility at the two Texas Class I areas. The higher visibility impairment in 1998 and 1999 suggests a downward trend but that may be just due to more adverse meteorological and natural emissions (e.g., wildfires) in these two years than any real long term trend.

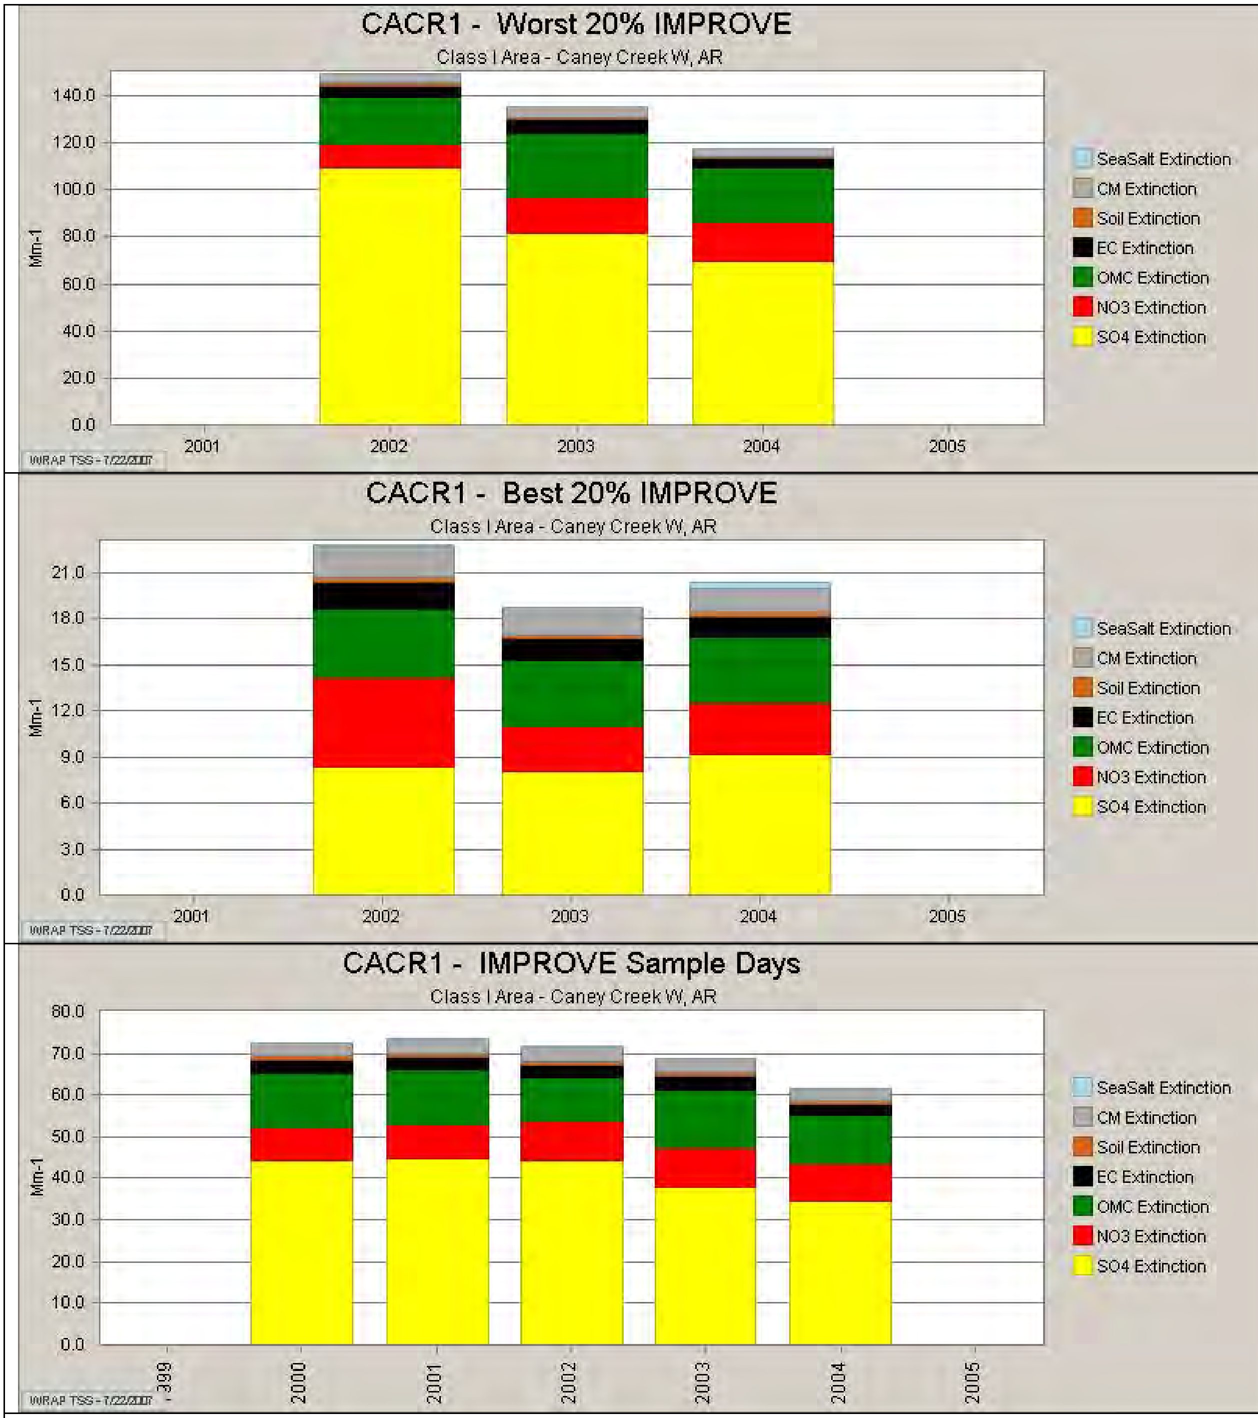

Figure 5-19a. Time series of observed IMPROVE reconstructed light extinction (New IMPROVE) at Caney Creek (CACR), Arkansas for the average of the Worst 20 Percent days (top), Best 20 Percent days (middle) days and all IMPROVE sampling days during the period of record.

APPENDIX A

Model Performance Evaluation of the 2002 36 km MM5 Meteorological Model Simulation used in the CENRAP Modeling and Comparison to VISTAS Final 2002 36 km MM5 and WRAP Interim 2002 36 km MM5 Simulations

The CENRAP 2002 36 km MM5 simulation (Johnson, 2007) was evaluated against observed surface and upper-air meteorological observations and observed precipitation amounts and its performance was compared against the VISTAS final and the WRAP interim 2002 36 km MM5 simulations. The CENRAP, VISTAS and WRAP 2002 36 km MM5 simulations used several common science options:

- Lambert Conformal Projection with center at (97°, 40°) and standard parallels at (33°, 45°).
- 164 by 128 36 km by 36 km horizontal grids covering the continental U.S. and adjacent regions.
- 34 vertical layers up to 100 mb (~15 km AGL).
- Pleim-Xiu Land Surface Module (LSM).
- Asymmetric Convective Mixing (ACM) Planetary Boundary Layer (PBL) model.
- RRTM long-wave radiation.
- Dudhia short-wave radiation.
- No Shallow convection.

However, there were some differences in the choice of science options:

- VISTAS and CENRAP MM5 simulations used the Kain Fritsch 2 cumulus parameterization, whereas WRAP MM5 used Kain Fritsch 1.
- VISTAS and CENRAP MM5 simulations used the Reisner 1 moist physics while WRAP MM5 used Reisner 2.
- All three MM5 simulations used Four Dimensional Data Assimilation (FDDA analysis nudging at the surface for winds, but WRAP also used surface analysis nudging to temperature and moisture.
- All three MM5 simulations used analysis nudging FDDA above the PNL to winds, temperature and moisture.

Much of the difference in the model performance for the three MM5 simulations was related to the surface temperature and moisture analysis nudging used in the interim WRAP MM5 simulations that resulted in better surface temperature model performance, but caused instabilities resulting in degradation in meteorological model performance above the surface. The final WRAP 2002 36 km MM5 simulation did not use the surface temperature and moisture FDDA and used the Betts-Miller cumulus scheme instead of Kain Fritsch that resulted in much improved meteorological model performance in the western States (Kemball-Cook et al., 2005).

A.1 Surface Meteorological Model Performance

The performance of the three MM5 simulations at the surface was evaluated through comparisons against observed surface wind, temperature and humidity measurements from the ds472 observational database. The METSTAT program was used to evaluate the MM5 simulations for each month of 2002 and across the 11 subdomains shown in Figure A-1. These subdomains are as follows:

1 = Pacific NW
2 = SW
3 = North
4 = Desert SW
5 = CenrapN
6 = CenrapS
7 = Great Lakes
8 = Ohio Valley
9 = SE
10 = NE
11 = MidAtlantic

Emery and Tai (2001) have developed model performance benchmarks by analyzing over 30 MM5RAMS meteorological model simulations and tabulating the typical level of performance that a good meteorological model achieves. These performance benchmarks are not intended to be pass/fail grades; rather they provide a framework to evaluate the model performance against past applications. Since many of the past MM5/RAMS meteorological model simulations that the benchmarks were developed from were in support of urban ozone modeling that are typically fairly stagnant conditions with little or no precipitation and involved multiple iterations to achieve the final base case simulation. Thus, we may not expect the 2002 annual MM5 simulations to achieve a similar level of performance given the complicating factors of precipitation and complex terrain associate with many Class I areas in the west. Table A-1 lists the meteorological model performance benchmarks for wind speed, wind direction, temperature and humidity.

Table A-1. Meteorological model performance benchmarks (Source: Emery et al., 1999).

Statistic	Wind Speed	Wind Direction	Temperature	Humidity
RMSE	≤ 2 m/s			
Mean Bias	≤ ±0.5 m/s	≤ ±10°	≤ ±0.5 K	≤ ±1.0 g/kg
Index of Agreement	≤ 0.6		≤ 0.8	≤ 0.6
Gross Error		≤ 30°	≤ 2.0 K	≤ 2.0 g/kg

Below we present the evaluation of the CENRAP, VISTAS and interim WRAP 2002 36 km MM5 simulations against surface meteorological observations for the four seasonal months of January, March, July and October and the CENRAP North (CenrapN) and CENRAP South (CenrapS) subdomains (i.e., subdomains 5 and 6 in Figure A-1). The surface evaluation of the three MM5 2002 36 km simulations outside of the CENRAP subdomains can be found in Kemball-Cook et al., (2004).

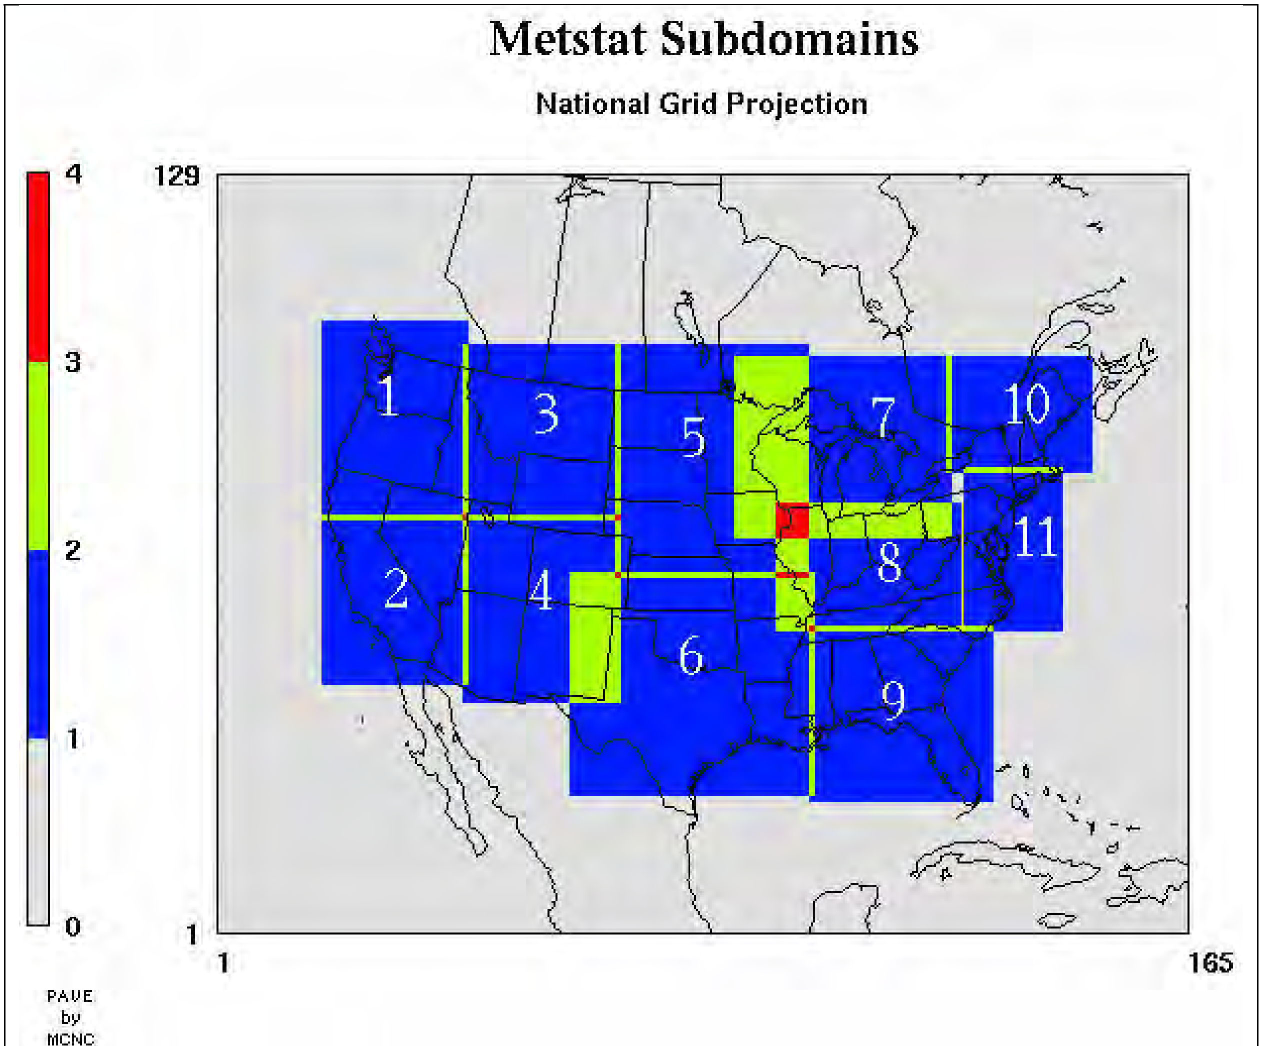

Figure A-1. Eleven subdomains where monthly evaluation of the MM5 simulations surface model performance was evaluated.

A.1.1 Temperature

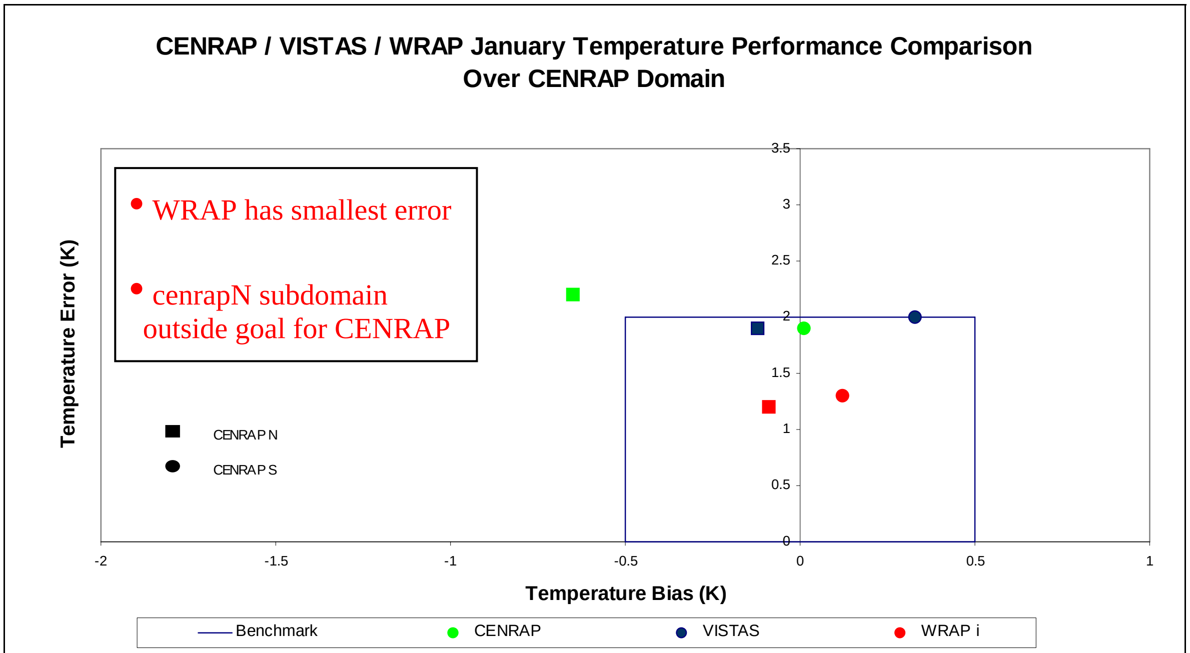
Figure A-2 displays the surface temperature model performance for the CENRAP, VISTAS and WRAP 2002 36 km MM5 simulations in the CenrapN and CenrapS subdomains and the months of January, March, July and October. The WRAP MM5 simulations are performing best for January temperature in both CENRAP domains exhibiting low bias and the lowest error that are within the benchmark. The VISTAS MM5 rum is performing next best with bias well within the benchmark and error within but close to the error benchmark. The CENRAP MM5 simulation performs well for the CenrapS domain with zero bias and error within, but approaching the benchmark. However, the CENRAP performance for the CenrapN domain does not achieve the performance benchmarks due to a too cold bias.

The temperature performance in March is similar to January with both the VISTAS and WRAP MM5 simulations achieving the benchmark for both CENRAP subdomains. Again the CENRAP MM5 simulation has a near zero bias and achieves the error benchmark in the CenrapS subdomain, but is too cold in the CenrapN domain falling out of the bias benchmark range.

In July the three simulations achieve the temperature benchmark in both CENRAP subdomains, although the WRAP MM5 simulations is cooler with the CenrapS bias right at the -0.5 K lower bound benchmark. The CENRAP MM5 simulation is slightly warmer than the VISTAS MM5 simulation.

In October, all three MM5 simulations achieve the temperature performance benchmarks. The WRAP MM5 simulation performs best with near zero bias and lower error than either the VISTAS or CENRAP simulations. The VISTAS and CENRAP MM5 simulations exhibit nearly identical temperature performance in October with a near zero bias for the CenrapS subdomain and a cool bias for the CenrapN subdomain.

In conclusion, the WRAP MM5 simulation is always performing best for surface temperature with the lowest bias and usually the lowest error. The VISTAS MM5 simulations is performing next best as the CENRAP MM5 simulations exhibits a cool bias for the CenrapN subdomain in January and March that exceed the performance benchmarks.



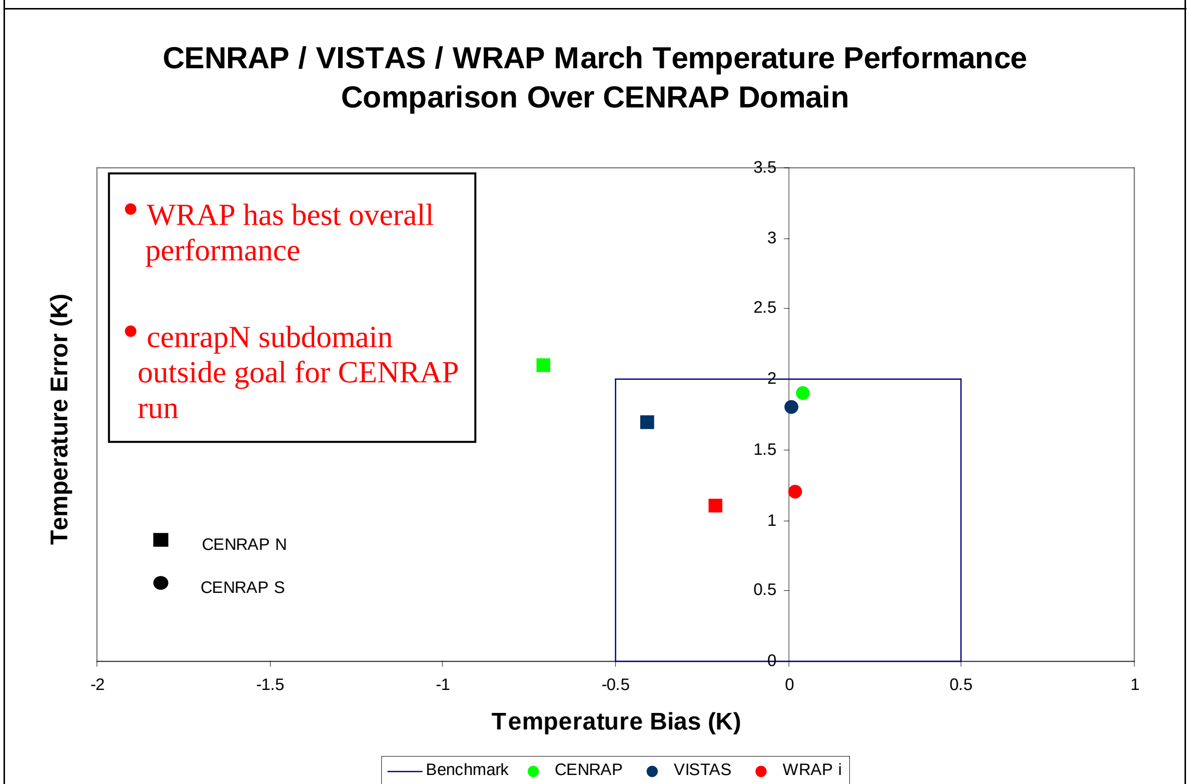


Figure A-2a. Temperature performance for the CENRAP, VISTAS and interim WRAP 2002 36 km MM5 simulations, the CenrapN and CenrapS subdomains and January (top) and March (bottom).

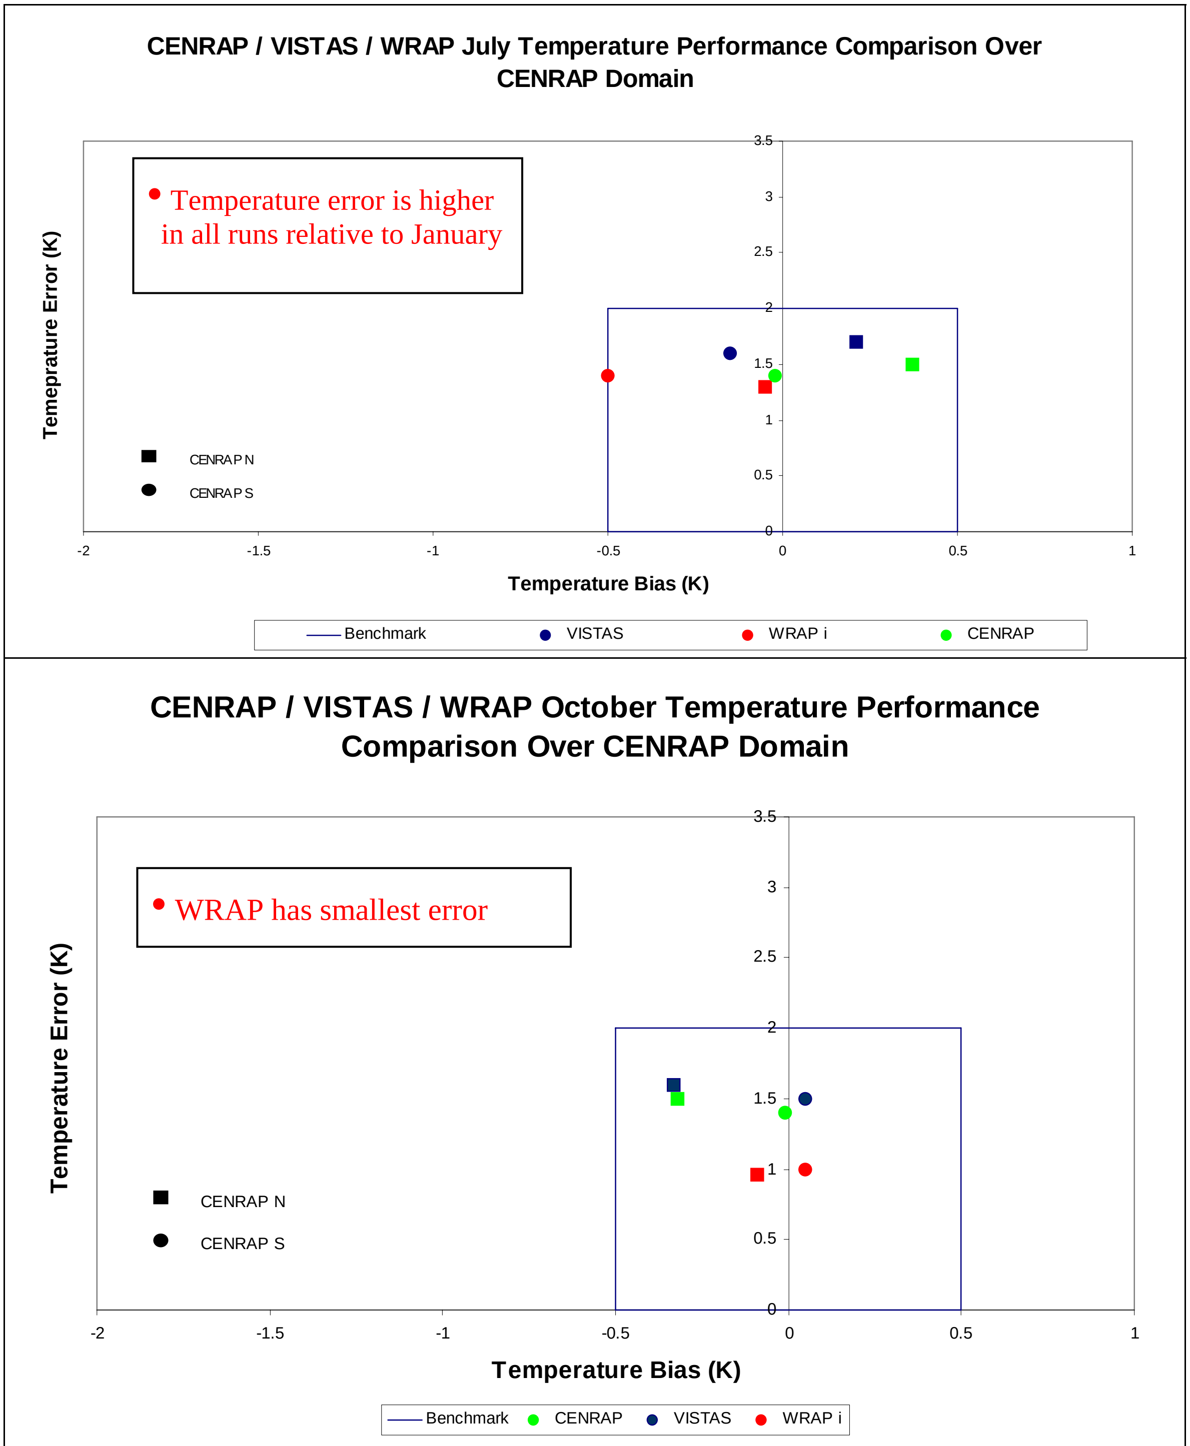

Figure A-2b. Temperature performance for the CENRAP, VISTAS and interim WRAP 2002 36 km MM5 simulations, the CenrapN and CenrapS subdomains and July (top) and October (bottom).

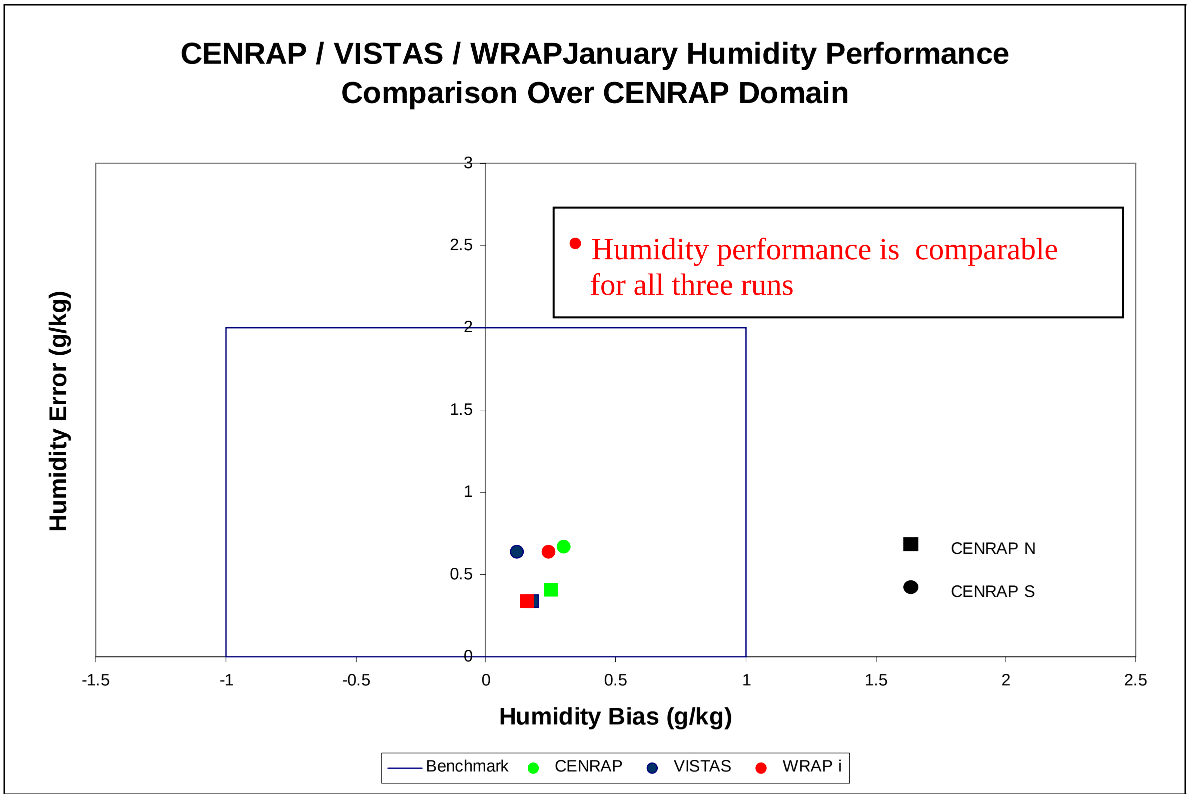
A.1.2 Humidity

The humidity performance for the three MM5 simulations is comparable and always achieves the performance benchmarks. The humidity bias is always near zero for all three runs and four months. In January, March and October the humidity error is at or less than half of the 2.0 g/kg benchmark. However, in July there is more error in the humidity with it within but approaching the benchmark value for all three models.

In conclusion, all three MM5 simulations achieved the humidity benchmark performance goals for all months studied. No model simulation exhibited superior performance over another.



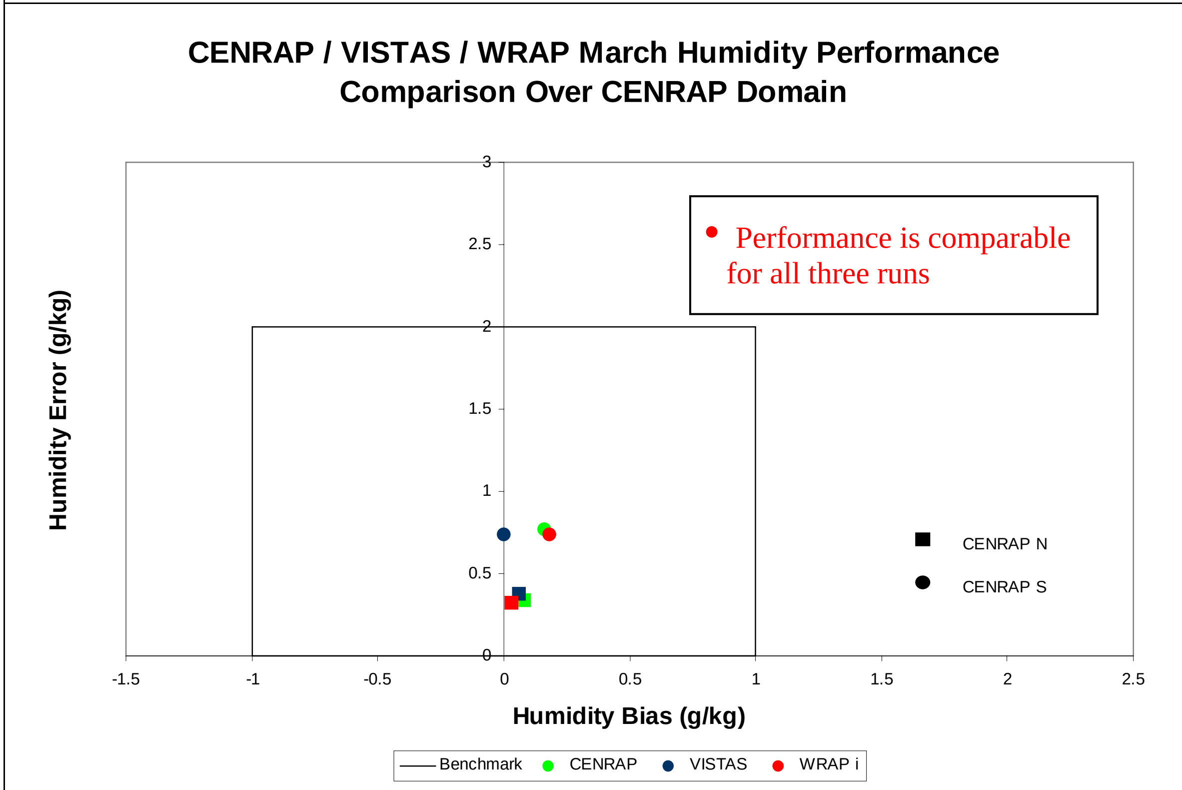


Figure A-3a. Humidity performance for the CENRAP, VISTAS and interim WRAP 2002 36 km MM5 simulations, the CenrapN and CenrapS subdomains and January (top) and March (bottom).

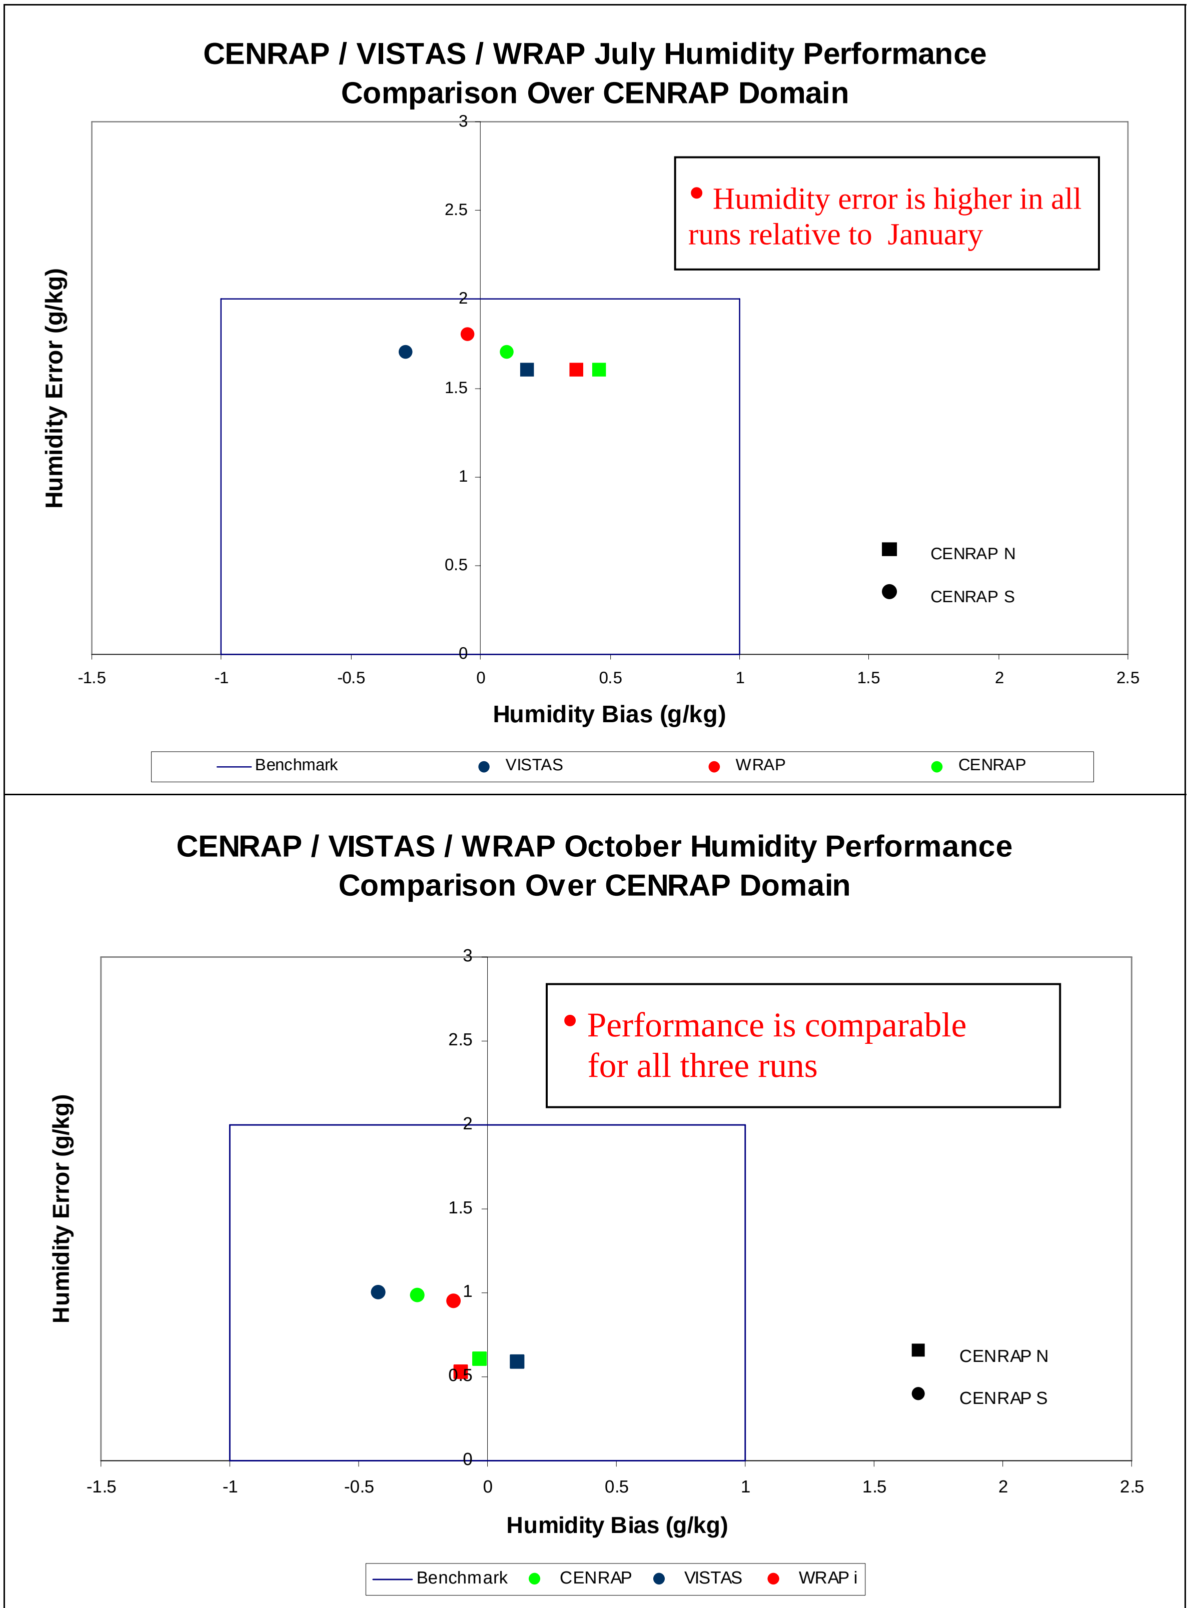

Figure A-3b. Humidity performance for the CENRAP, VISTAS and interim WRAP 2002 36 km MM5 simulations, the CenrapN and CenrapS subdomains and July (top) and October (bottom).

A.1.3 Winds

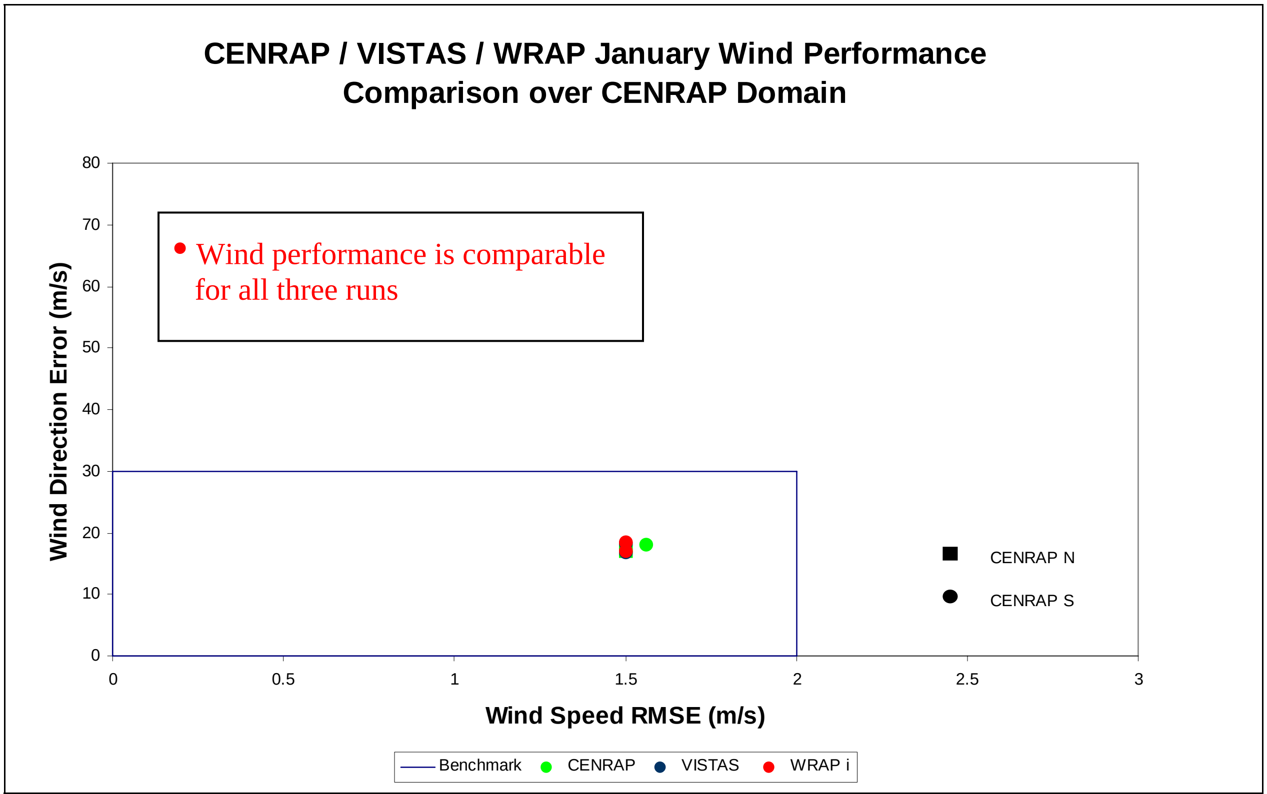
The model performance for wind speed and direction and January is almost identical and within the benchmarks for all three models and both CENRAP subdomains. In fact, the performance is so close the CenrapS symbols are plotted over and obliterate the CenrapN performance symbols.

In March, the wind performance is within the benchmark for all three MM5 simulations, which exhibit similar performance statistics. The wind performance in the CenrapS subdomain is slightly better than CenrapN with the CENRAP MM5 simulations showing the largest wind speed RMSE in the CenrapN subdomain, although still within the benchmarks.

Slight degraded wind direction performance is seen in July with the error increases to just below 20 degrees to just below the 30 degree benchmark value for all three models. Similar wind speed RMSE is seen for all three models.

The October wind performance is within the benchmarks for all three models with performance between that seen for January/March and July.

In summary, the models exhibited similar model performance for surface wind speed and direction.



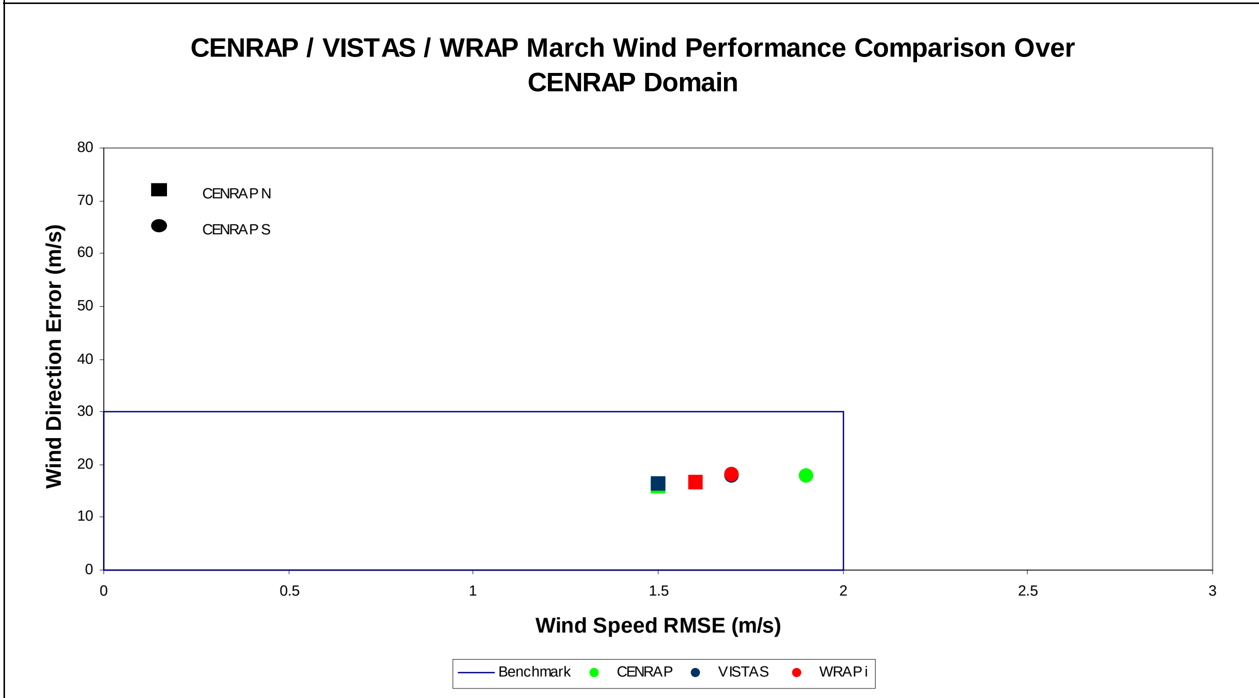


Figure A-4a. Wind Speed and Wind Direction performance for the CENRAP, VISTAS and interim WRAP 2002 36 km MM5 simulations, the CenrapN and CenrapS subdomains and January (top) and March (bottom).

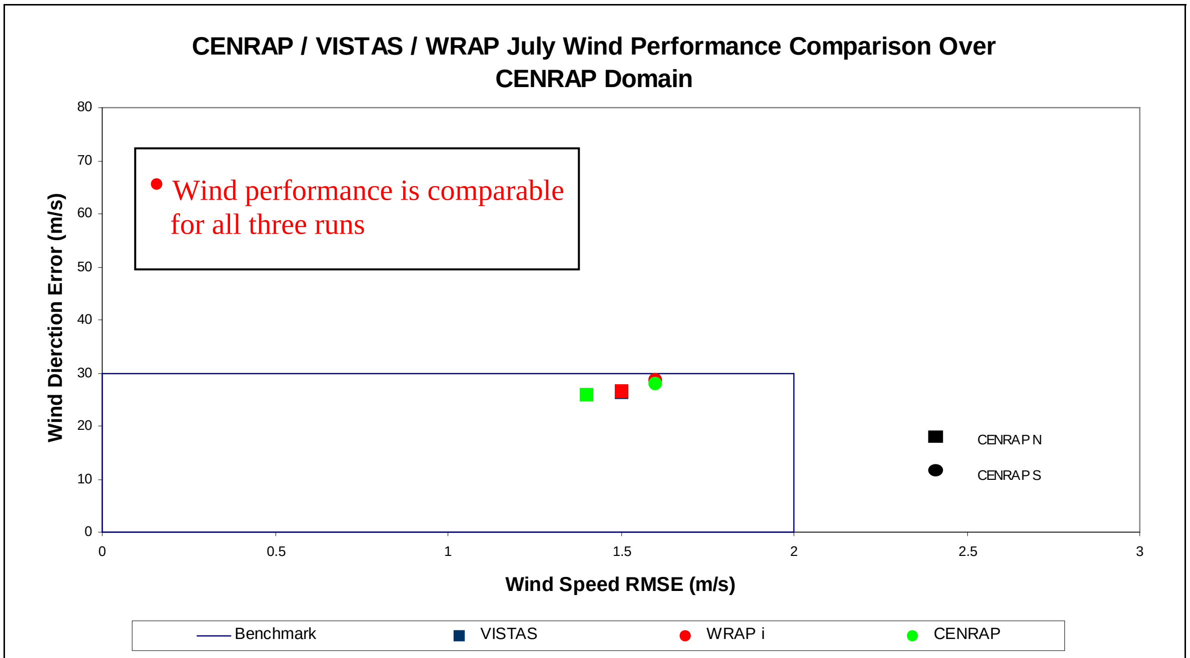

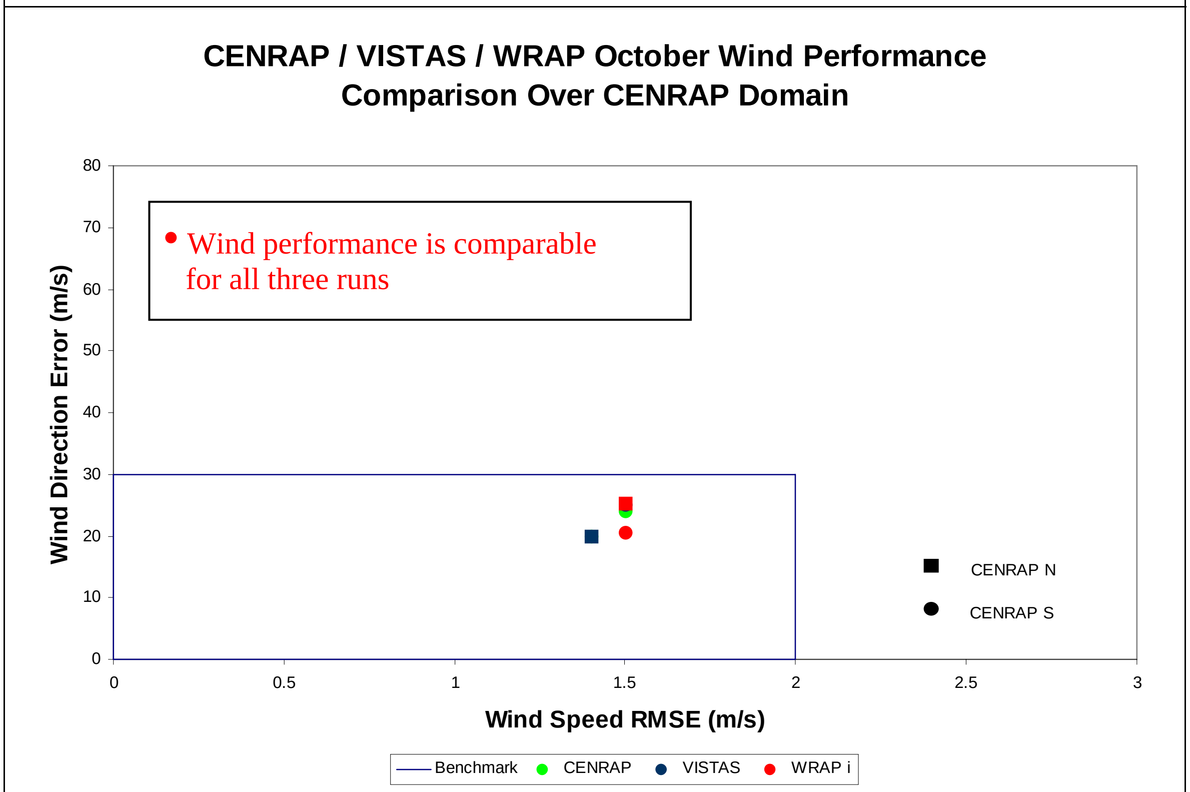

Figure A-4b. Wind Speed and Wind Direction performance for the CENRAP, VISTAS and interim WRAP 2002 36 km MM5 simulations, the CenrapN and CenrapS subdomains and July (top) and October (bottom).

A.2 Upper-Air Meteorological Evaluation

Figure A-5 displays an example comparison of the vertical profile of predicted and observed winds and temperature for Midland, Texas and January 7 2002 at 12 GMT (6am LST) and for July 16, 2002 at 00 GMT (6pm LST). Above the surface, all three models do a good job in replicating the observed temperature, dew point temperature and winds at 6a on January 7, 2002. Although the WRAP MM5 simulation predicts the surface temperature better than the other two simulations, the vertical structure of the temperature and the surface temperature inversion is not reproduced as well.

All three models understate the afternoon PBL depth on July 16, 2002 at Midland Texas. This phenomenon was seen at other sites as well.

The upper-air meteorological model evaluation found that all three models had difficulty reproducing the observed nocturnal inversion. The day time convective mixing depths were also typically underestimated.

Although the WRAP MM5 simulation reproduced the surface temperature the best of the three models, it was worst at reproducing the observed vertical temperature structure and resultant level of mixing. These results are likely due to the surface data assimilation of temperature employed by the WRAP interim MM5 simulation and resulted in WRAP eliminating the surface temperature and humidity FDDA in their final simulation.

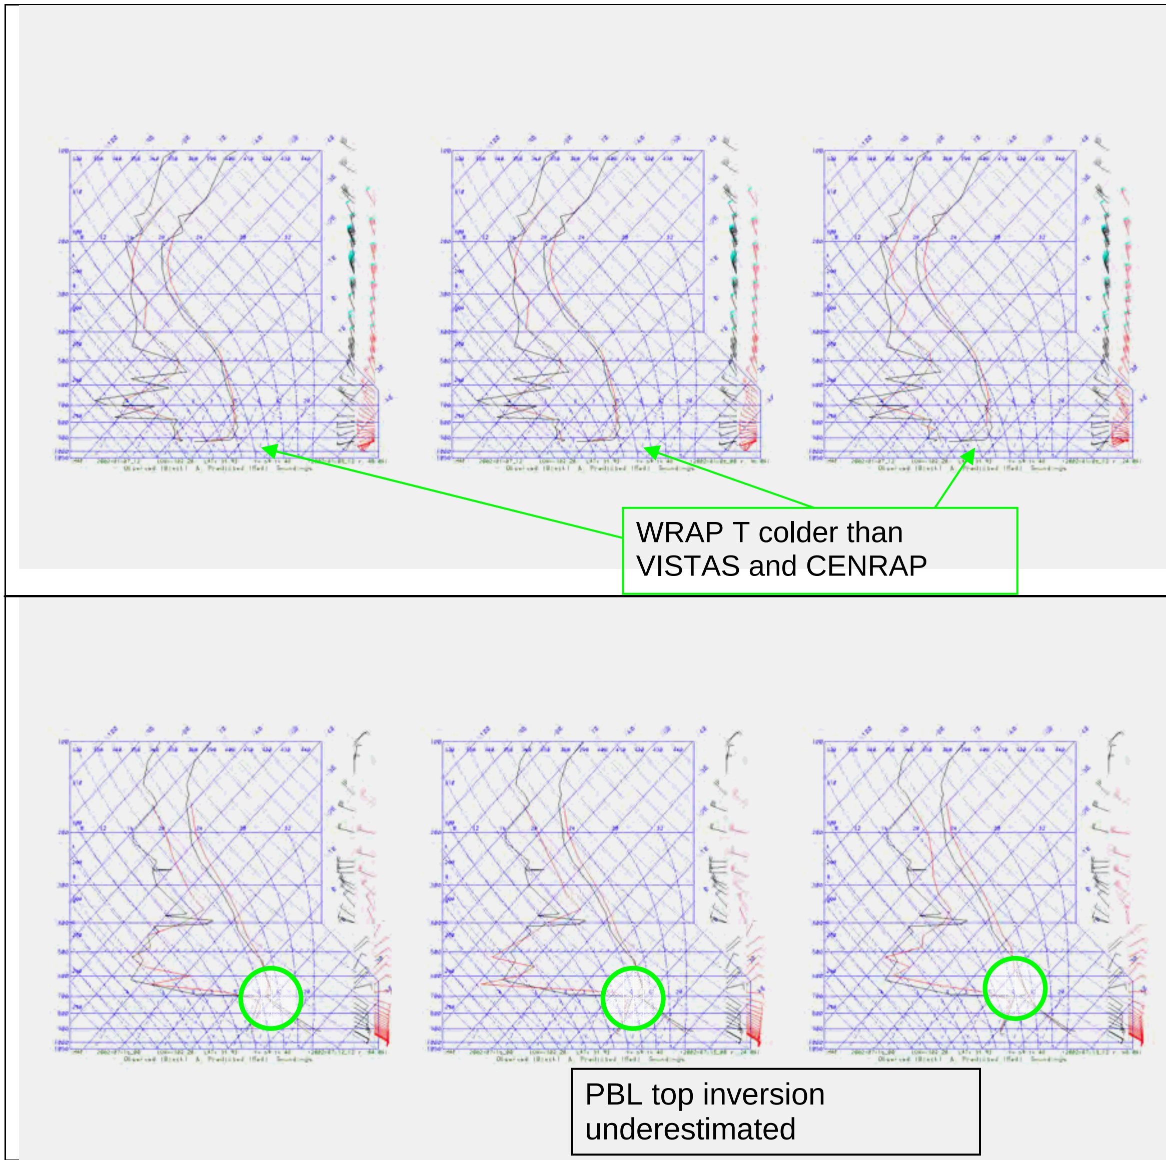

Figure A-5. Comparison of predicted and observed vertical temperature, dew point and winds profiles for the CENRAP (left), VISTAS (middle) and WRAP (right) at Midland Texas on January 7, 2002 at 12 GMT (top) and July 16, 2002 at 00 GMT (bottom).

A.4 Precipitation Model Performance Evaluation

The three MM5 model simulation precipitation estimates were evaluated by comparing the monthly average spatial distributions and amounts with observed values from the observed CPC 0.25 by 0.25 degree (approximately 28 km by 28 km) gridded analysis fields. The CPC analysis fields are gridded from on U.S. land-based observations, consequently the gridded observed fields are not available over the oceans and Canada and Mexico. The CPC observed monthly average precipitation fields were displayed using the MM5 modeling domain. The MM5 total precipitation estimates were accumulated for a month and plotted. Here total precipitation includes both explicit large scale synoptic precipitation as well as the subgrid-scale convective precipitation from the cumulus parameterization (Kain Fritsch 1 or 2).

Figures A-6 through A-9 display the monthly average precipitation fields for the months of January, March, July and October and the CPC observed and CENRAP, VISTAS and interim WRAP MM5 simulations. In January (Figure A-6), all three models reproduce the observed monthly average precipitation well with enhanced predicted and observed precipitation over the Pacific Northwest and the Appalachian Mountains. The MM5 simulations also estimated enhanced precipitation in off-shore areas north of Seattle, over the Atlantic Ocean and in the Gulf of Mexico that can not be either confirmed or refuted by the CPC observations. MM5 does overstate the amount of precipitation in January over the northern CENRAP region including over Minnesota, Iowa and Nebraska.

The three models also do a good job in reproducing the observed spatial distribution and amounts of the precipitation in March 2002 (Figure A-7). Elevated precipitation areas in the Pacific Northwest and across the lower Midwest from Arkansas and up into the Ohio River Valley and adjacent areas. The MM5 simulations do understate the highest observed precipitation amounts in Arkansas. The MM5 simulations also overstate the amount of precipitation in the desert southwest (Four Corners) area in March.

The MM5 monthly average precipitation performance is dramatically worse in July 2002 (Figure A-8). Precipitation is overstated by all three MM5 simulations throughout the U.S. and particularly in the southern states, from Arkansas across Texas to the southeastern U.S. particularly Florida South and North Carolina. This over-prediction bias is due to convective precipitation from the cumulus parameterization (either Kain Fritsch 1 or 2). This overactive precipitation is the result of the over-prediction bias I humidity seen in many subdomains (see Table A-3b and Kemball-Cook et al., 2004a).

In October 2002, the three MM5 simulations reproduced the observed monthly average rainfall fairly well across the U.S. (Figure A-9). The models predict the location of the maximum precipitation in southern Louisiana well, but under-predict the magnitude, which may be due to a slight spatial displacement offshore in the Gulf of Mexico. The MM5 simulations understate the precipitation over the CENRAP region, which explains the dry humidity bias in the CenrapS subdomain in October (Figure A-3b).

In conclusion, the three MM5 simulations do a good job in simulating the observed precipitation when it is due to synoptic weather systems. However, when precipitation is due to convective activity as seen in July that is simulated by the MM5 cumulus parameterization, MM5 greatly overstates the precipitation amounts. This is particularly pronounced in the southern states from the Four Corners area to Florida with the interim WRAP simulation exhibiting the largest over-prediction bias. In the final WRAP MM5 simulation the Betts-Miller cumulus parameterization was used that greatly reduced the convective precipitation amounts resulting in better model performance (Kemball-Cook et al., 2005). However, an overestimation bias under convective precipitation conditions still was present.

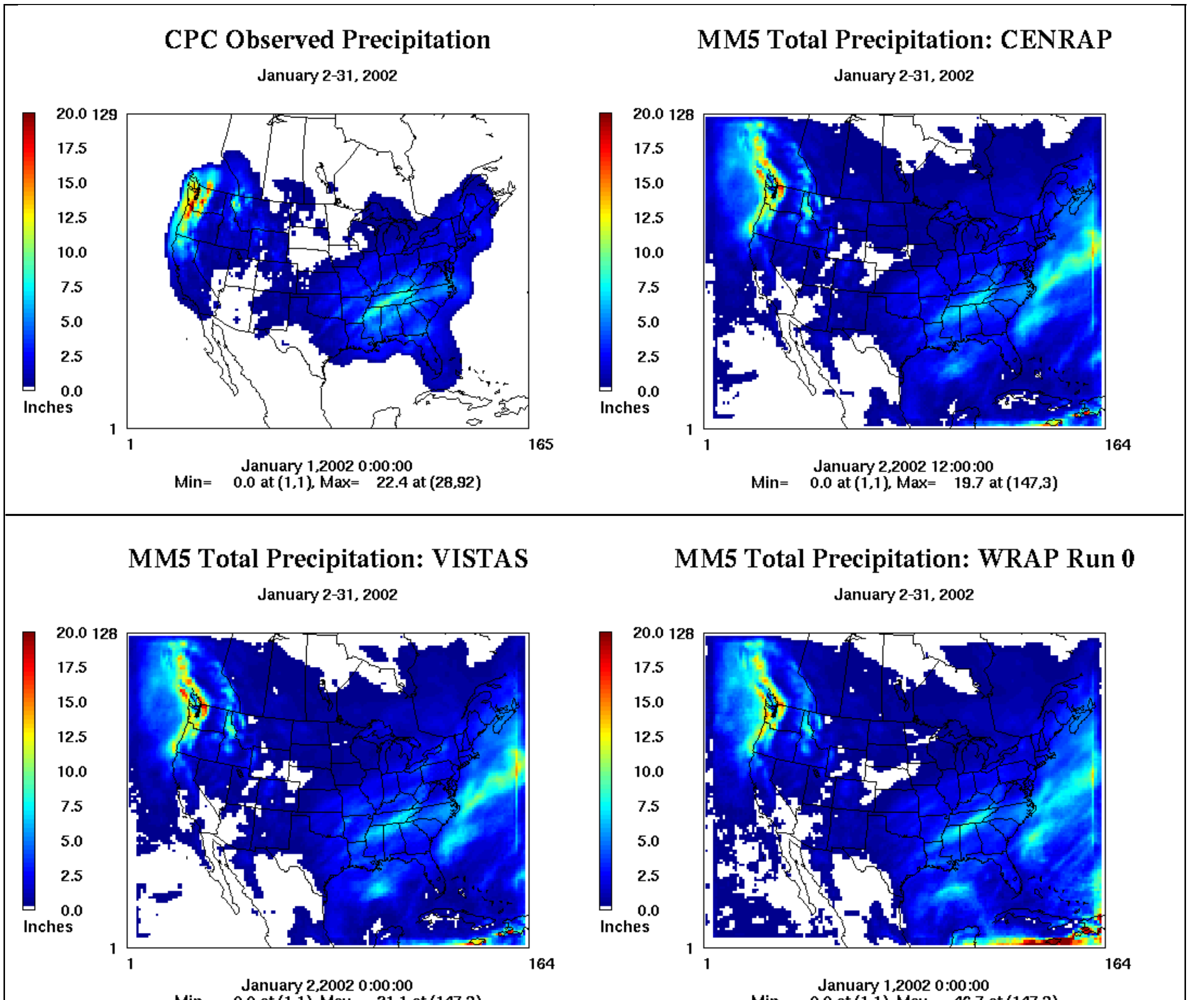

Figure A-6. Comparison of January 2002 observed monthly average precipitation (top left) with predicted values for the CENRAP (top right), VISTAS (bottom left) and WRAP (bottom right January 2002 simulation (note: observed precipitation not valid over water due to lack of measurements).

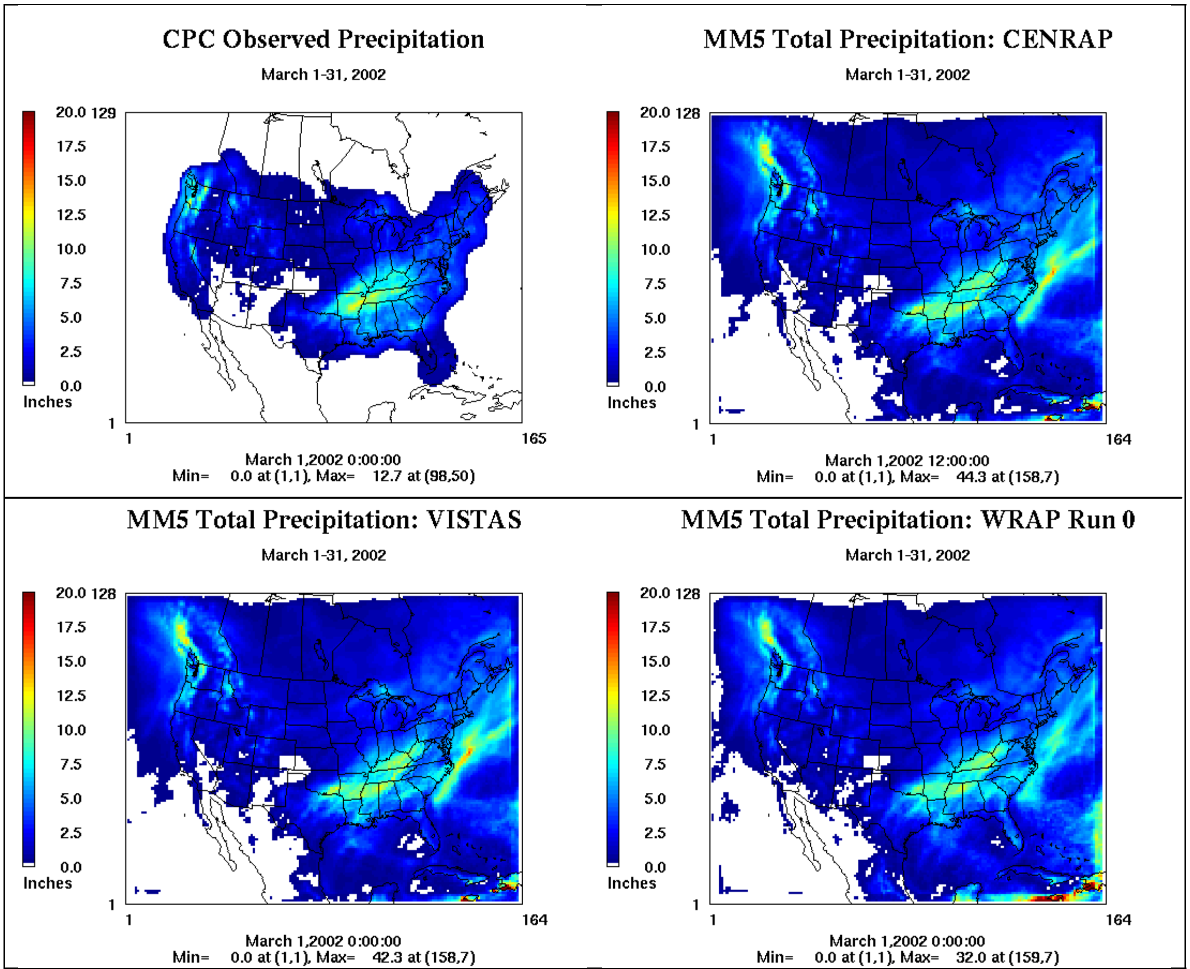

Figure A-7. Comparison of March 2002 observed monthly average precipitation (top left) with predicted values for the CENRAP (top right), VISTAS (bottom left) and WRAP (bottom right January 2002 simulation (note: observed precipitation not valid over water due to lack of measurements).

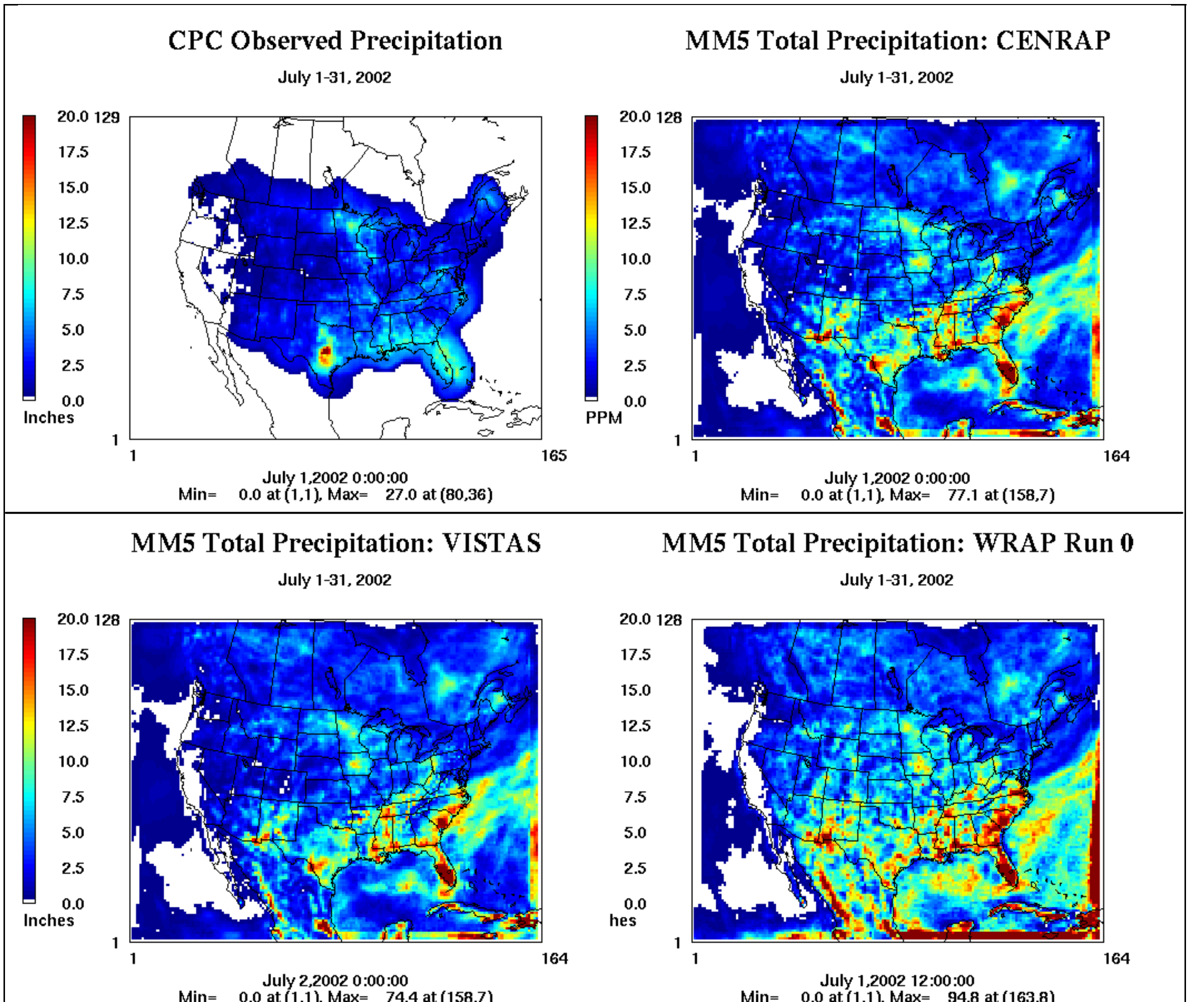

Figure A-8. Comparison of July 2002 observed monthly average precipitation (top left) with predicted values for the CENRAP (top right), VISTAS (bottom left) and WRAP (bottom right) (note: observed precipitation not valid over water due to lack of measurements).

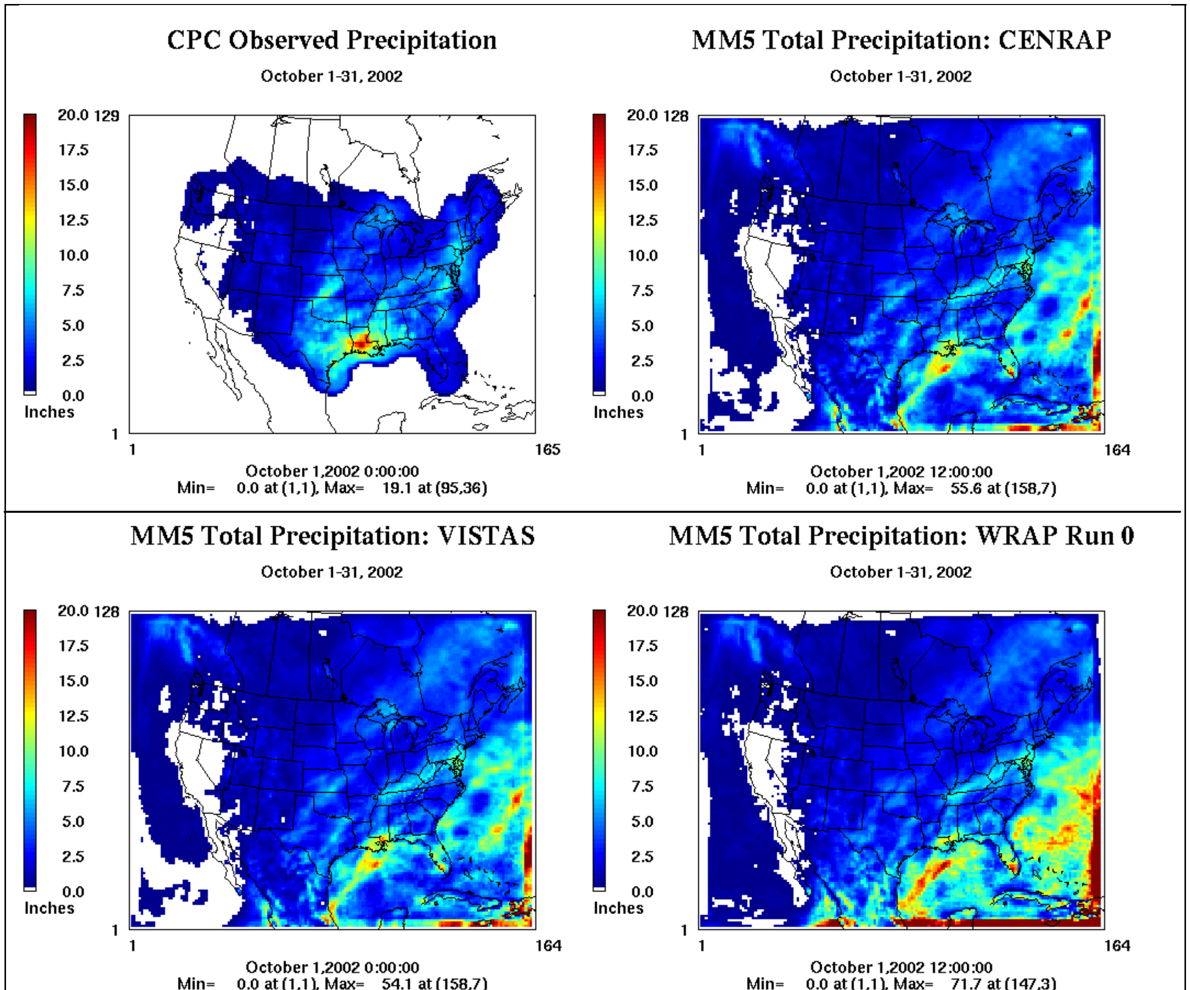

Figure A-9. Comparison of October 2002 observed monthly average precipitation (top left) with predicted values for the CENRAP (top right), VISTAS (bottom left) and WRAP (bottom right) (note: observed precipitation not valid over water due to lack of measurements).

APPENDIX C

Model Performance Evaluation for the CMAQ 2002 Base F Base Case Simulation in the CENRAP Region

C.1 2002 Typical Base F Model Performance Evaluation Scenario

This Appendix presents the operational evaluation of the CMAQ model for the 2002 36 km Typical Base F emissions scenario. The final CENRAP 2002 and 2018 emissions scenarios used in the 2018 visibility projections was Base G. The main differences between Base G and Base F emissions inventories were updated Mexican emissions in the northern states, addition of Mexican emissions in the southern states that were not included in CENRAP's emission inventories prior to Base G and correction of a few point source stack parameters and emissions in the CENRAP states and Canada (see: http://pah.cert.ucr.edu/aqm/cenrap/QA_typ02g36.plots/log_inv_categ_Typ02g.doc). Figure C-1 displays the differences in annual average $PM_{2.5}$ and ozone concentrations between the 2002 Typical Base G and Base F simulations. Most of the differences in the two simulations are concentrations within Mexico where no monitoring data were available for the model evaluation. Thus, given the very small differences between the 2002 Typical Base F and G base case simulations, the model performance evaluation is presented for just the 2002 Typical Base F simulation (for additional comparisons of Base G and F see: http://pah.cert.ucr.edu/aqm/cenrap/cmaq.shtml#typ02gvstyp02f_mpe).

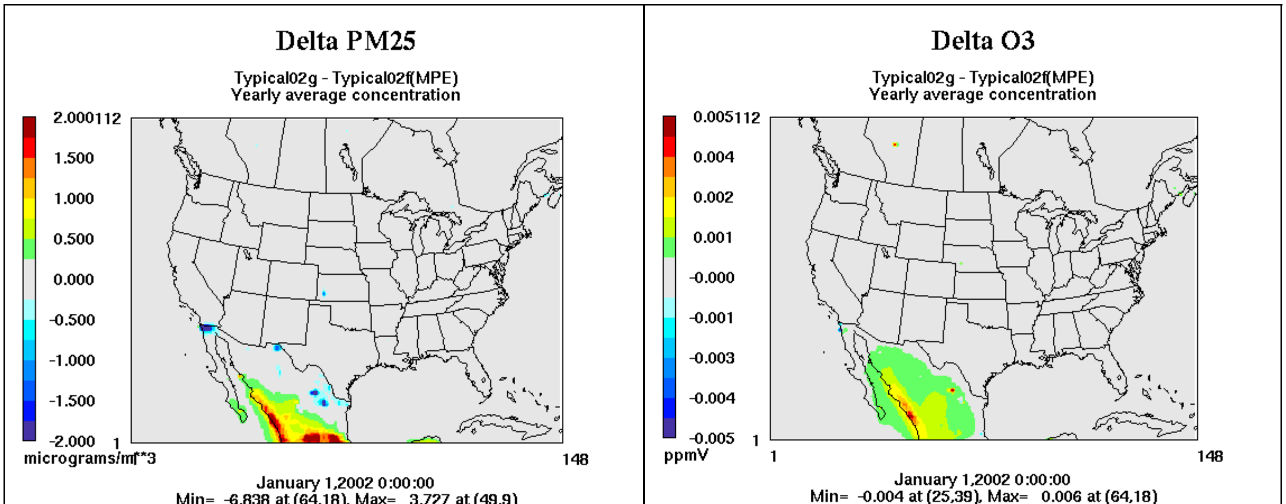

Figure C-1. Comparison of differences in annual average $PM_{2.5}$ (left) and ozone concentrations between 2002 Typical Base G and F (Base G – Base F).

The CENRAP emissions and air quality modeling initially conducted 2002 base case modeling for two 2002 base case emissions scenarios: a 2002 Actual emissions base case; and a 2002 Typical emissions base case. For the 2002 Actual base case, day-specific SO2 and NOx emissions for large stationary point sources were used based on measured continuous emissions monitoring (CEM) data along with actual 2002 fire emissions In the 2002 Typical base case, emissions for large stationary sources and fires were more representative of the 2000-2004 Baseline period. For large stationary sources' typical emissions, 5-years of CEM data were analyzed and typical seasonal and diurnally varying emissions were defined for when the sources where operating For the typical fire emissions, the locations of the 2002 Actual fire emissions were retained, but the intensity was reduced or increased to match the average conditions over the 5-year Baseline. The original intent of the CENRAP modeling of both a 2002 Actual and Typical base cases was to use the 2002 Actual base case for the model performance evaluation and the 2002 Typical base case with the 2018 emission scenario for the 2018 visibility projections.

The need to generate both the 2002 Typical and Actual base case inventories and perform CMAQ model simulations each time an emissions update or correction to the modeling occurred became burdensome and potentially could compromise the CENRAP schedule and available resources. For the Base F vintage emissions database, a model performance evaluation was conducted that compared the model performance of the 2002 Actual and Typical Base F CMAQ base case simulations to determine whether use of the Actual emissions substantially changed the interpretation of the model performance. The maximum change in model performance between the 2002 Actual and Typical base case was for sulfate and occurred during the summer months, when sulfate is the highest. Figure C-2 displays sulfate (SO4), nitrate (NO3), elemental carbon (EC) and organic matter carbon (OMC) performance for July 2002 across IMPROVE sites in the CENRAP region for the 2002 36 km Actual and Typical Base F CMAQ base case simulations. Although differences in predicted 24-hour SO4 concentrations are sometimes discernable in the scatter plot, the basic model performance conclusions remains the same and the difference in fractional bias (-48% vs. -49%) and fraction error (58% vs. 59%) are not significant. Similarly, the difference in NO3 model performance between the Actual and Typical Base F simulations are not significant. The performance of the CMAQ Actual and Typical simulation for EC and OMC is essentially identical. Given the similarity of the 2002 Base F Actual and Typical model performance evaluation, future CENRAP CMAQ model performance analysis were just performed on the Typical simulation.

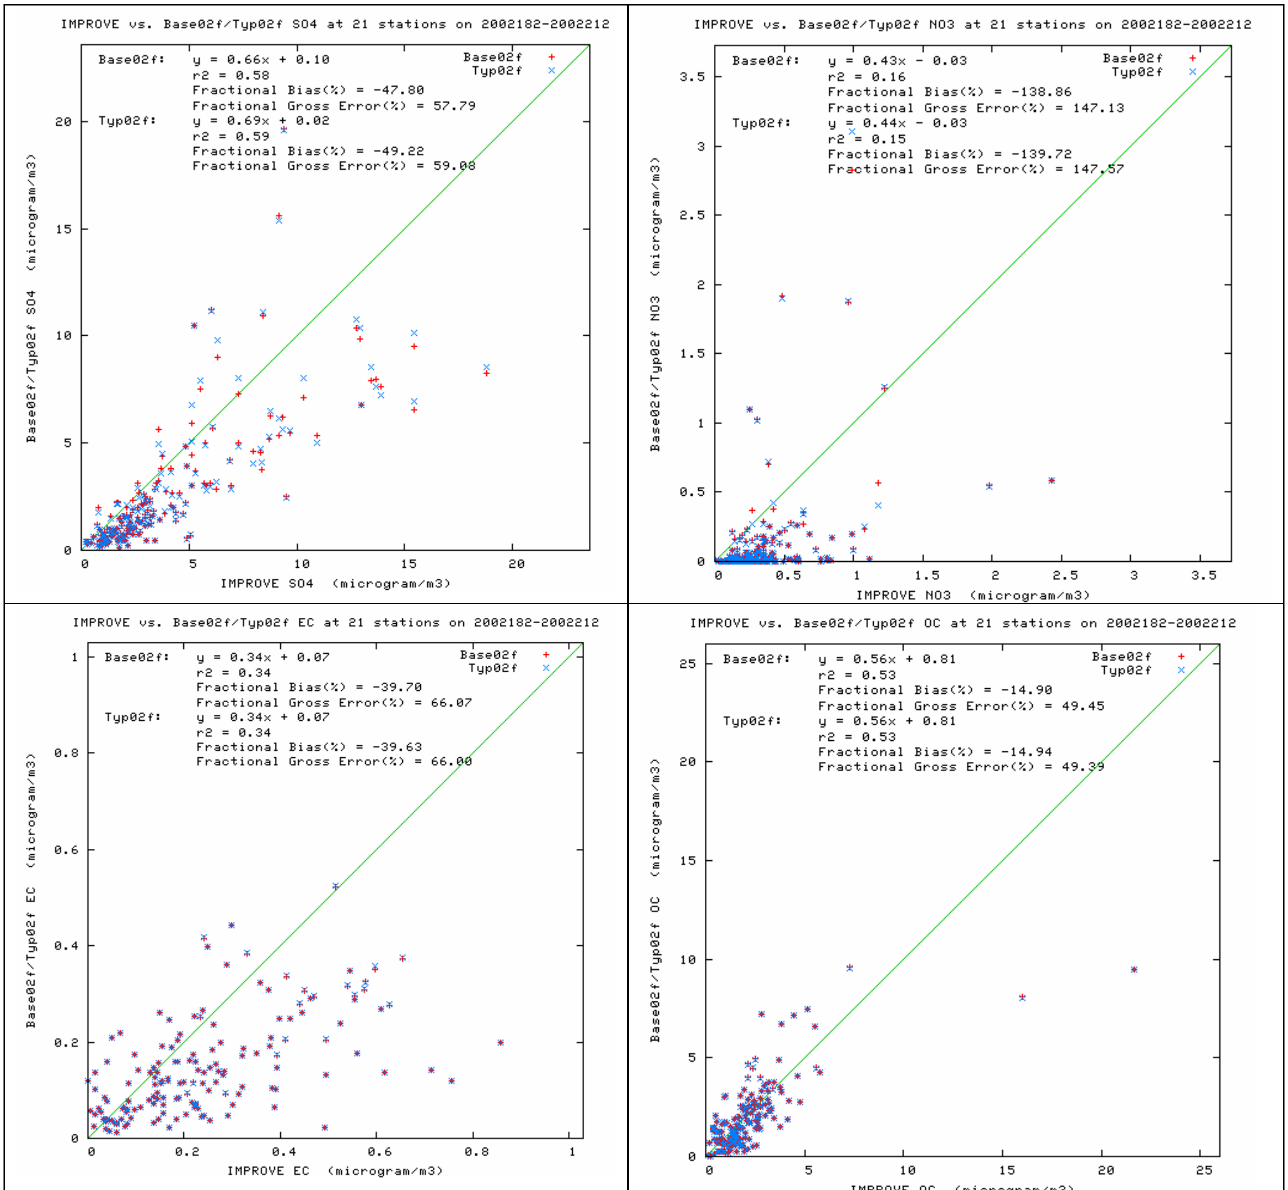

Figure C-2. Comparison of SO4 (top left), NO3 (top right), EC (bottom left) and OMC (bottom right) model performance for July 2002, the CENRAP region and the 2002 36 km Base F Actual (red) and Typical (blue) CMAQ base case simulation.

C.2 CMAQ Evaluation Methodology

EPA's integrated ozone, $PM_{2.5}$ and regional haze modeling guidance calls for a comprehensive, multi-layered approach to model performance testing, consisting of the four major components: operational, diagnostic, mechanistic (or scientific) and probabilistic (EPA, 2007). The CMAQ model performance evaluation effort focused on the first two components, namely:

- **Operational Evaluation**: Tests the ability of the model to estimate PM concentrations (both fine and coarse) and the components at PM_{10} and $PM_{2.5}$ including the quantities used to characterize visibility (i.e., sulfate, nitrate, ammonium, organic carbon, elemental carbon, other $PM_{2.5}$, and coarse matter ($PM_{2.5-10}$). This evaluation examines whether the measurements are properly represented by the model predictions but does not necessarily ensure that the model is getting "the right answer for the right reason"; and

- **Diagnostic Evaluation:** Tests the ability of the model to predict visibility and extinction, PM chemical composition including PM precursors (e.g., SOx, NOx, and NH_3) and associated oxidants (e.g., ozone and nitric acid); PM size distribution; temporal variation; spatial variation; mass fluxes; and components of light extinction (i.e., scattering and absorption).

The diagnostic evaluation also includes the performance of diagnostic tests to better understand model performance and identify potential flaws in the modeling system that can be corrected. The diagnostic evaluation may also includes the use of "probing tools" to understand why the model obtains a given prediction; probing tools include Process Analysis (PA), decoupled direct method (DDM) and source apportionment (SA).

In this final model performance evaluation for the 2002 Typical Base F CMAQ simulation, the operational evaluation has been given the greatest attention since this is the primarily thrust of EPA's modeling guidance. However, we have also examined certain diagnostic features dealing with the model's ability to simulate sub-regional and monthly/diurnal gas phase and aerosol concentration distributions. In the course of the CENRAP and other modeling process numerous diagnostic sensitivity tests were performed to investigate and improve model performance. Key diagnostic tests performed are discussed and the results for the rest are available on the CENRAP modeling website: http://pah.cert.ucr.edu/aqm/cenrap/index.shtml.

C.2.1 Ambient Air Quality Data for CENRAP Model Evaluation

The ground-level model evaluation database for 2002 was compiled by the modeling team using several routine and research-grade databases. The first is the routine gas-phase concentration measurements for ozone, NO, NO_2 and CO archived in EPA's Aerometric Information Retrieval System (AIRS) Air Quality System (AQS) database. Other sources of observed information come from the various PM monitoring networks in the U.S. These include the: (a) Interagency Monitoring of Protected Visual Environments (IMPROVE); (b) Clean Air Status and Trends Network (CASTNET); (c) Southeastern Aerosol Research and Characterization (SEARCH); (d) EPA Federal Reference Method $PM_{2.5}$ and PM_{10} Mass Networks (EPA-FRM); (e) EPA Speciation Trends Network (STN) of $PM_{2.5}$ species; and (f) National Acid Deposition Network (NADP). These PM

monitoring networks may also provide ozone and other gas phase precursors and product species, and visibility measurements at some sites. During the course of the CENRAP modeling, the numerous base case simulations were evaluated across the continental U.S. In this section we focus our evaluation on model performance within the CENRAP region. Table C-1 summarizes the observations collected at each monitoring network within the CENRAP region and their sampling frequency with Figure C-3 displaying the locations of the monitors for the various monitoring networks operating in the CENRAP region during 2002.

Table C-1. Ambient monitoring data available in the CENRAP region during 2002.

Monitoring Network	Chemical Species Measured	Sampling Frequency; Duration
IMPROVE	Speciated $PM_{2.5}$ and PM_{10}	1 in 3 days; 24 hr
CASTNET	Speciated $PM_{2.5}$, Ozone	Hourly, Weekly; 1 hr, Week
SEARCH	24-hr PM_{25} (FRM Mass, OC, BC, SO_4, NO_3, NH_4, Elem.); 24-hr PM coarse (SO_4, NO_3, NH_4, elements); Hourly $PM_{2.5}$ (Mass, SO_4, NO_3, NH_4, EC, TC); and Hourly gases (O_3, NO, NO_2, NO_y, HNO_3, SO_2, CO)	Daily, Hourly;
NADP	WSO_4, WNO_3, WNH_4	Weekly
EPA-FRM	Only total fine mass ($PM_{2.5}$)	1 in 3 days; 24 hr
EPA-STN	Speciated $PM_{2.5}$	Varies; Varies
AIRS/AQS	CO, NO, NO_2, NO_x, O_3	Hourly; Hourly

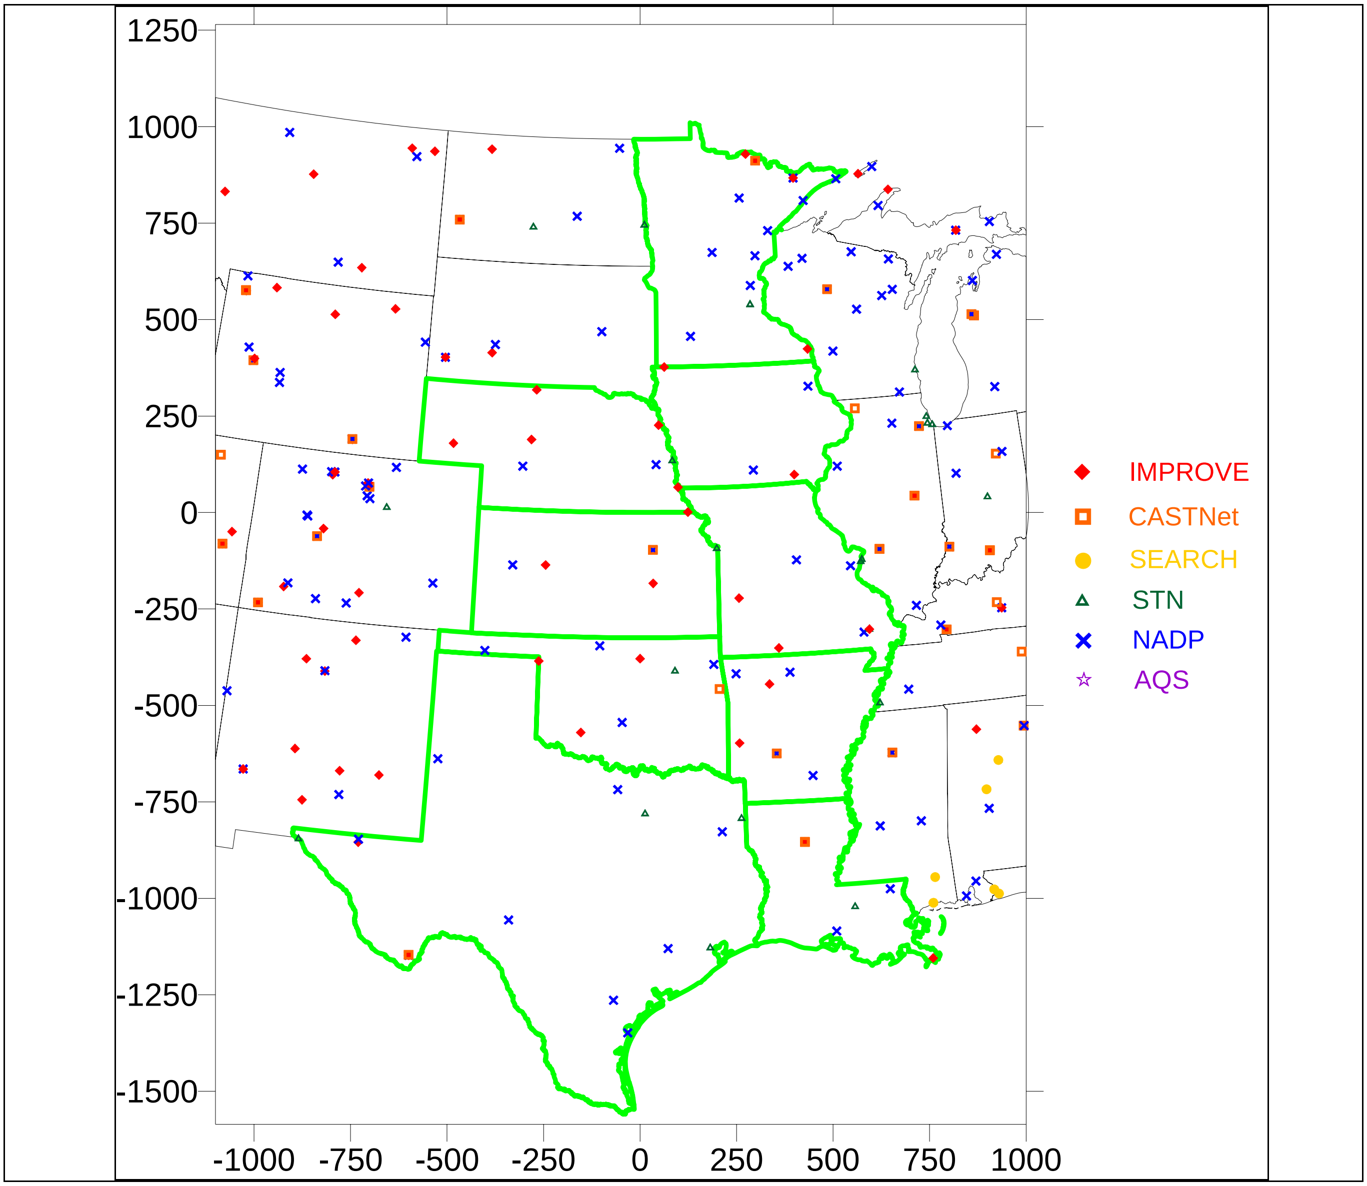

Figure C-3. Locations of surface monitors within the CENRAP states for sites operating during 2002.

C.2.2 Scope of CMAQ Model Performance Evaluation

The primary focus of the CMAQ Base F evaluation is on how well the model is able to replicate observed concentrations gas-phase pollutants and precursors, the various components of $PM_{2.5}$, total observed mass of $PM_{2.5}$, and wet deposition amounts. The CMAQ operational evaluation, model outputs are compared statistically and graphically with observational data obtained from the IMPROVE, CASTNet, STN, NADP and AQS monitoring networks. Because the SEARCH network is located in the southeastern U.S. (VISTAS region) outside of the CENRAP region, it is not a major component of our evaluation. Also, since the EPA-FRM network focuses on just $PM_{2.5}$ mass measurements primarily in $PM_{2.5}$ nonattainment or near nonattainment areas it is not very relevant for simulating regional haze at mainly remote Class I areas so is also not used in our model performance evaluation. The primary focus of the operational evaluation of the CMAQ 2002 Base F simulation is the performance of PM components in the CENRAP region for predicting regional haze at Class I areas.

Many statistical performance measures have been calculated using the different monitoring networks and across the different model performance subdomains (e.g., RPO regions). Table C-2 lists the definitions of the model performance evaluation statistical metrics. These performance metrics are routinely generate by the UCR Analysis Tool and are available on the project website. Many of them are measures of bias and error that are somewhat redundant.

Table C-2. Statistical Measures Used in the CENRAP CMAQ Model Evaluation.

Statistical Measure	Shorthand Notation	Mathematical Expression	Notes
Accuracy of paired peak (***A_p***)	**Paired_Peak**	$\frac{P - O_{peak}}{O_{peak}}$	P_{peak} = paired (in both time and space) peak prediction
Coefficient of determination (***r^2***)	**Coef_Determ**	$\frac{\left[\sum_{i=1}^{N}(P_i - \overline{P})(O_i - \overline{O})\right]^2}{\sum_{i=1}^{N}(P_i - \overline{P})^2 \sum_{i=1}^{N}(O_i - \overline{O})^2}$	P_i = prediction at time and location i; O_i = observation at time and location i; $\overline{P}$ = arithmetic average of P_i, i=1,2,…, N; $\overline{O}$ = arithmetic average of O_i, i=1,2,…,N
Normalized Mean Error (***NME***)	**Norm_Mean_Err**	$\frac{\sum_{i=1}^{N}\lvert P_i - O_i\rvert}{\sum_{i=1}^{N} O_i}$	Reported as %
Root Mean Square Error (***RMSE***)	**Rt_Mean_Sqr_Err**	$\left[\frac{1}{N}\sum_{i=1}^{N}(P_i - O_i)^2\right]^{1/2}$	Reported as %
Fractional Gross Error (***F_E***)	**Frac_Gross_Err**	$\frac{2}{N}\sum_{i=1}^{N}\left\lvert\frac{P_i - O_i}{P_i + O_i}\right\rvert$	Reported as %

Mean Normalized Bias (***MNB***)	**Mean_Norm_Bias**	$\frac{1}{N}\sum_{i=1}^{N}\frac{(P_i - O_i)}{O_i}$	Reported as %
Mean Fractionalized Bias (Fractional Bias, ***MFB***)	**Mean_Fract_Bias**	$\frac{2}{N}\sum_{i=1}^{N}\left(\frac{P_i - O_i}{P_i + O_i}\right)$	Reported as %
Normalized Mean Bias **(*NMB*)**	**Norm_Mean_Bias**	$\frac{\sum_{i=1}^{N}(P_i - O_i)}{\sum_{i=1}^{N}O_i}$	Reported as %
Bias Factor (***BF***)	**Bias Factor**	$\frac{1}{N}\sum_{i=1}^{N}\left(\frac{P_i}{O_i}\right)$	Reported as BF:1 or 1: BF or in fractional notation (BF/1 or 1/BF).

C.2.3 Operational Model Evaluation Approach

The CENRAP modeling databases will be used to develop the visibility State Implementation Plan (SIP) due in December 2007 as required by the Regional Haze Rule (RHR). Accordingly, the primary focus of the operational evaluation is on the six components of fine particulate ($PM_{2.5}$) and Coarse Matter ($PM_{2.5\text{-}10}$) within the CENRAP region that are used to characterize visibility at Class I areas:

- Sulfate (SO4);
- Particulate Nitrate (NO3);
- Elemental Carbon (EC);
- Organic Mass Carbon (OMC);
- Other inorganic fine particulate (IP or Soil); and
- Coarse Matter (CM).

The model performance for ozone and precursor and product species (e.g., SO_2 and HNO_3) is also evaluated to build confidence that the modeling system is sufficiently reliable to project future-year visibility.

C.2.5 Performance Evaluation Tools

One of the many challenges in evaluating an annual PM/ozone model simulation is how to synthesize model performance given the shear volume of output from an annual simulation. The model is run on a 148 x 112 x 19 grid with approximately 30 species producing hourly outputs for each day of the year. This results in approximately 90 trillion concentration estimates that are produced for an annual simulation. Thus, the synthesis and interpretation of numerous graphical and tabular displays of model performance into a few concise and descriptive displays that identify the most salient features of model performance is necessary. As part of the CENRAP modeling, as well as work performed by WRAP, VISTAS, MRPO and MANE-VU, several analysis tools and summary displays have been developed and are used:

<u>UCR Analysis Tools</u>: The University of California at Riverside (UCR) Analysis Tools have been used extensively to evaluate the CMAQ and CAMx models for CENRAP (e.g., Morris et al., 2005), WRAP (Tonnesen et al., 2004), VISTAS (Morris et al., 2004) as well as other studies and are run on a Linux platform separately for each network. Numerous graphical displays of model performance are automatically generated using gnuplot. The software generates the following summary and graphical displays of model performance:

- Tabular statistical measures (see Table C-2);
- Time Series Plots for each site and species; and
- Scatter Plots for each species by allsite_allday, allday_onesite and allsite_oneday.

The UCR Analysis Tool is run for a specific subregion (e.g., by RPO region) and for selected monitoring networks. Because each monitoring network has its own measurement artifacts, the model is evaluated separately for each monitoring network.

<u>Summary Bias/Error Plots</u>: The modeling team has developed additional displays of model performance statistics that elucidate model performance in a concise manner: (1) monthly time series plots of average bias and error; (2) soccer plots that display bias versus error and compares them to model performance goals and criteria; and (3) tools to analyze visibility model performance for the worst and best 20 percent visibility days that are used in visibility projections.

<u>GA DNR Analysis Plots</u>: Dr. James Boylan of the Georgia Department of Natural Resources has extended the concept in EPA's draft PM fine particulate and regional haze modeling guidance that model performance for species that make up a major contribution to visibility impairment be subjected to more stringent goals than species that are minor contributors by developing concentration-dependent performance goals and "Bugle Plots" to display them (Boylan, 2004).

The evaluation of the CENRAP 2002 36 km Base F CMAQ simulation used each of the analysis tools listed above taking advantage of their different descriptive and complimentary nature. The use of these analysis tools generated thousands of statistical measures and graphical displays of model performance that cannot all be displayed in this report. The modeling team has gone through the plots and measures using slide shows to identify those displays that are most descriptive in conveying model performance so should be included in this TSD. The complete set of model performance statistics and graphical performance displays can be found on the CENRAP modeling Website at:

http://pah.cert.ucr.edu/aqm/cenrap/cmaq.shtml#cmaq_typ02f_mpe

Note that model performance statistics are calculated separately for each of the monitoring networks. Different PM measurement technology can produce different measurement values even when measuring the same air parcel. Thus, when calculating model performance metrics, measurements in different networks are not mixed.

C.2.4 Subdomains Analyzed

CENRAP has been analyzing model performance in five subdomains corresponding to the states contained in the five RPOs (see Figure 1-1):

- CENRAP
- MRPO
- VISTAS
- MANE-VU
- WRAP

As CENRAP has refined its emissions inventory, the changes in model performance from one 2002 base case to another has diminished to the point where little has changed in the last few iterations. Thus, the CMAQ 2002 36 km Base F evaluation presented in this section was just performed for the CENRAP region and the reader is referred to the modeling Website (http://pah.cert.ucr.edu/aqm/cenrap/cmaq.shtml) and Morris and co-workers (2005) for the evaluation outside of the CENRAP region and the diagnostic model evaluation.

C.2.5 Model Performance Goals and Criteria

The issue of model performance goals for PM species is an area of ongoing research and debate. For ozone modeling, EPA has established performance goals for 1-hour ozone normalized mean bias and gross error of #±15% and #35%, respectively (EPA, 1991). EPA's draft fine particulate modeling guidance notes that performance goals for ozone should be viewed as upper bounds of model performance that PM models may not be able to always achieve and we should demand better model performance for PM components that make up a larger fraction of the PM mass than those that are minor contributors (EPA, 2001). EPA's final modeling guidance does not list any specific model performance goals for PM and visibility modeling and instead provides a summary of PM model performance across several historical applications that can be used for comparisons if desired. Measuring PM species is not as precise as ozone monitoring. In fact, the differences in measurement techniques for some species likely exceed the more stringent performance goals, such as those for ozone. For example, recent comparisons of the PM species measurements using the IMPROVE and STN measurement technologies found differences of approximately ∀20% (SO4) to ∀50% (EC) (Solomon et al., 2004).

For the CENRAP, VISTAS and WRAP modeling we have adopted three levels of model performance goals and criteria for bias and gross error as listed in Table C-3. Note that we are not suggesting that these performance goals be adopted as guidance or that they are the most appropriate goals to use. Rather, we are just using them to frame and put the PM model performance into context and to facilitate model performance intercomparison across episodes, species, models and sensitivity tests.

Table C-3. Model performance goals and criteria used to assist in interpreting modeling results.

Fractional Bias	Fractional Error	Comment
#∀15%	#35%	Ozone model performance goal for which PM model performance would be considered good – note that for many PM species measurement uncertainties may exceed this goal.
#∀30%	#50%	Proposed PM model performance goal that we would hope each PM species could meet
#∀60%	#75%	Proposed PM criteria above which indicates potential fundamental problems with the modeling system.

As noted in EPA's PM modeling guidance, less abundant PM species should have less stringent performance goals (EPA, 2001; 2007). Accordingly, we are also using performance goals that are a continuous function of average concentrations, as proposed by Dr. James Boylan at the Georgia Department of Natural Resources (GA DNR), that have the following features (Boylan, 2004):

- Asymptotically approaching proposed performance goals or criteria (i.e., the ∀30%/50% and ∀60%/75% bias/error levels listed in Table C-1) when the mean of the observed concentrations are greater than 2.5 ug/m^3.
- Approaching 200% error and ∀200% bias when the mean of the observed concentrations are extremely small.

Bias and error are plotted as a function of average concentrations. As the mean concentration approach zero, the bias performance goal and criteria flare out to ∀200% creating a horn shape, hence the name "Bugle Plots". Dr. Boylan has defined three Zones of model performance: Zone 1 meets the ∀30%/50% bias/error performance goal and is considered "good" model performance; Zone 2 lies between the ∀30%/50% performance goal and ∀60%/75% performance criteria and is an area where concern for model performance is raised; and Zone 3 lies above the ∀60%/75% performance criteria and is an area of questionable model performance.

C.2.6 Performance Time Periods

The CMAQ 2002 36 km Base F evaluation, model performance statistics and graphical displays are generated monthly using the native averaging times of each monitoring network (i.e., 24-hour for IMPROVE and STN; weekly for CASTNet and NADP; and hourly for AQS). As the focus of the RHR is on daily average visibility that is calculated from daily average PM species concentrations then the evaluation of the model for 24-hour concentrations is particularly relevant. The RHR places particular emphasis on the Worst 20% (W20%) and Best 20% (B20%) days at Class I areas. Thus, we also place particular emphasis on the model performance for PM species on the W20% and B20% days during 2002 at Class I areas.

C.2.7 Key Measures of Model Performance

Although we have generated numerous statistical performance measures (see Table C-2) that are available on the CENRAP modeling website, when comparing model performance across months, subdomains, networks, grid resolution, models, studies, etc. it is useful to have a few key measurement statistics to be used to facilitate the comparisons. It is also useful to have a subset of the 2002 year that can represent the entire year so that a more focused evaluation can be conducted. We have found that the Mean Fractional Bias and Mean Fractional Gross Error appear to be the most consistent descriptive measure of model performance (Morris et al., 2004b; 2005). The Fractional Bias and Error normalize by the average of the observed and predicted value (see Table C-2) because it provides descriptive power across different magnitudes of the model and observed concentrations and is bounded by -200% to +200%. This is in contrast to the normalized bias and error (as recommended for ozone performance goals, EPA, 1991) that is normalized by just the observed value so can "blow up" to infinity as the observed value approaches zero. Below we perform a focused evaluation of model performance for four months of the 2002 year that are used to represent the seasonal variation in performance:

- January
- April
- July
- October

We also present fractional bias and error for all months of 2002 using time series and bugle plots.

C.3 Operational Model Performance Evaluation in the CENRAP Region

In the following discussions we use selected monthly scatter plots, time series plots and model performance statistical measures from the UCR Analysis Tools application to the 2002 CMAQ Base F base case simulation in an operational evaluation of the model for PM species. We focus on the six main components of PM that are used to project visibility.

C.3.1 Sulfate (SO4) Monthly Model Performance

C.3.1.1 SO4 in January 2002

Figure C-4a displays scatter plots of predicted and observed SO4 concentrations or wet depositions for sites in the CENRAP regions using observations from the IMPROVE, STN, CASTNet and NADP monitoring networks; the IMPROVE and STN SO4 concentrations are 24-hour averages whereas the CASTNet SO4 concentrations and NADP SO4 wet deposition are weekly averages. The January SO4 performance at the IMPROVE and STN networks in the CENRAP region is quite good with low fractional bias (-12% to -13%) and some scatter (fractional error of 42% and 34%) but centered in the 1:1 line of perfect agreement. There is a net SO4 underestimation bias in January across the CASTNet network (fractional bias of -34%) with wet SO4 deposition overstated on average across the NADP sites in the CENRAP region (+40% fractional bias). Whether the overstated SO4 wet deposition is a contributor to the SO4 concentration underestimation bias is unclear, but it is in the correct direction to account for it.

The time series comparisons of predicted and observed 24-hour SO4 concentrations at CENRAP Class I area IMPROVE sites during January 2002 shown in Figure C-4b are quite encouraging. Although there are some days and sites with mismatches (e.g., January 26 at BOWA and VOYA) and sites with systematic performance problems (SO4 underestimated at BIBE), the time series in generally are quite good with the model tracking the observed temp[oral variation in daily sulfate in January and some sites exhibiting remarkable agreement (e.g., MING).

Figure C-4c displays the spatial variations in the predicted and IMPROVE observed SO4 concentrations for January 20, 23, 26 and 29, 2002, which are four consecutive days of IMPROVE monitoring using its 1:3 day monitoring frequency. On January 20 both the model and observations agree on that an elevated sulfate clouds is entering the CENRAP region across southern Illinois and Missouri. There is a sharp SO4 concentration gradient going east to west with both the model and observations estimating relatively clean SO4 values over Colorado. By January 23 the model and observations agree that elevated SO4 exists along a diagonal orientation from Chicago to East Texas. Although there are some SO4 model/observed spatial mismatches on this day (e.g., northern Louisiana and western Arkansas) the model generally reproduces the areas of elevated and low observed SO4. By January 29 the model and observations agree that SO4 has cleaned out of the CENRAP region. Although there are elevated SO4 observations in western North Dakota and northern Minnesota not reflected in the model. On January 29 there is an elevated tongue of SO3 entering the CENRAP region through southern Illinois stretching to the southwest almost to Big Bend in western Texas. Observed SO4 is measured at Big Bend but the modeled high SO4 is slightly east of there. There is very good agreement on this day between the predicted and observed spatial distribution of SO4.

C.3.1.2 SO4 in April 2002

In April CMAQ underestimates the observed SO4 in the CENRAP region with fractional bias values of -52%, -30% and -58% across the IMPROVE, STN and CASTNet networks (Figure C-5a). The fractional bias for wet SO4 deposition is quite low (3%) albeit with a lot of scatter which is reflected in high fractional error (78%). The ability of the model to reproduce the temporal variability of the April observed SO4 concentrations at the IMPROVE sites is quite variable. The SO4 under-prediction bias is clearly present at several sites (e.g., HEGL, BIBE and GUMO), whereas there is quite good agreement at others (UPBU, BRET and VOYA). Comparisons of the spatial distributions of the predicted and observed SO4 concentrations on April 5, 8, 11 and 14 are shown in Figure C-5c. On April 5 the model reproduces the half circle of elevated SO4 across Texas-Louisiana, but appears to not be as large an area as observed coming up short from some of the sites (e.g., BIBE and GUMO). Model and observations agree that April 8 is a relatively low SO4 day in the CENRAP region with just a small intrusion of elevated values across Mississippi. On April 14 the model has two separate clouds of elevated SO4, one over East Texas-Louisiana and one over northeastern Illinois and eastward with a clean area in between in southern Missouri. The observations agree except that it has these two elevated SO4 areas connected with the southern Missouri area not as clean as in the model.

C.3.1.3 SO4 in July 2002

SO4 concentrations are also underestimated by CMAQ in July (Figure C-6a) with fractional bias value ranging from -22 to -52%. Wet SO4 deposition is slightly overstated (22%) with a lot of scatter (83% error). The July SO4 under-prediction bias is also reflected in the time series plots (Figure C-6b). Comparisons of the predicted and observed spatial distribution of SO4 in the CENRAP region for July 7, 10, 13 and 16, 2002 are shown in Figure C-6c. In general the model and observations agree on the locations of the elevated SO4, except that the observed extent is somewhat larger so that the modeled elevated SO4 fails to impact some of the sites on the edge of the elevated cloud of SO4 (e.g., Big Bend, Guadalupe Mountains and northwestern Oklahoma).

C.3.1.4 SO4 in October 2002

In October 2002, CMAQ is doing a better job of reproducing the observed SO4 concentrations with much lower fractional bias values (-6%, 0% and -23%) and fractional errors < 40% (Figure C-7a). The observed SO4 time series are also reproduced well by the model, although an under-prediction bias is clearly evident at Big Bend, Guadalupe Mountains and Wichita Mountains. The model also reproduces the observed spatial distribution of SO4 well in October (Figure C-7c).

C.3.1.5 SO4 Monthly Bias and Error

Figure C-8 compares the monthly SO4 fractional bias and error across the CENRAP region for the three monitoring networks. The under-prediction bias is clearly evident the first 8-10 months of the year. This underestimation bias is greatest across the CASTNet network which persists through out the year and is least for the STN network where it disappears by August-September. The monthly SO4 fractional errors are generally between 30% and 60% and are greatest in the summer when SO4 concentrations are the highest.

Figure C-9 presents a Bugle Plot of monthly So4 fractional bias and error statistics and compares them against the proposed PM model performance goal and criteria (see Table C-3). For the STN network, it appears that SO4 performance for all months achieves the proposed PM model performance goal. For the IMPROVE network, approximately half of the months achieve the proposed PM performance goal with the other half exceed the goal but within the performance criteria. Across the CASTNet network most months exceed the proposed goal and are within the criteria. Although the CASTNet fractional bias for some months is right at the criteria (≤±60%). With the exception of two IMPROVE months, all of the monthly SO4 fractional error performance statistics achieve the proposed PM model performance goal.

C.3.2 Nitrate (NO3) Monthly Model Performance

The following sections discuss the monthly NO3 model performance across the IMPROVE, STN and CASTNet monitoring networks in the CENRAP region.

C.3.2.1 NO3 in January 2002

January NO3 CMAQ model performance is characterized by an overestimation bias across the CENRAP region (Figure C-10a). The fractional bias values for the IMPROVE, STN and CASTNet networks are 38%, 29% and 61%. Unlike SO4, wet deposition of NO3 is also overstated in January (43%). Fractional errors range from 90%-100% for the IMPROVE and CASTNet networks and are lower (54%) for the STN network and higher (114%) for the NADP network.

With the exception of Breton Island and Big Bend, the model NO3 over-prediction bias occurs at the other 8 CENRAP Class I areas (Figure C-10b). The observed time series is reproduced reasonable well at a couple sites, such as Wichita Mountains and the first half of January for Voyageurs. However, for most sites the observed NO3 time series is not reproduced very well and is extremely poorly reproduced for Breton Island, Big Bend and Guadalupe Mountains.

The model typically estimates a larger area of elevated NO3 concentrations than is observed. This is shown for January 20, 23, 26 and 29 in Figure C-10c. Whereas the model exhibits large areas of brown indicated daily average NO3 concentrations of 4 $\mu g/m^3$ or higher, the observed values of this high rarely occur and are usually limited to the central Illinois site. On January 20 the model estimates the entire eastern half of the CENRAP region should be covered by elevated NO3 concentrations, whereas the observations indicate much lower values. On January 23 the modeled elevated NO3 concentrations lies between the IMPROVE monitoring sites, although the central Illinois site suggests high NO3 did occur in the region. The observations on January 26 also suggest lower NO3 than the model is predicting. On January 29 the model estimates elevated NO3 from the central Illinois site to Wichita Mountains, Oklahoma that is supported by these two observations. In general, the model is estimating more wide-spread elevated NO3 concentrations than observed, whereas the observations suggest that the elevated NO3 occurrences is less frequent and more spotty.

C.3.2.2 NO3 in April 2002

Unlike the NO3 overestimation bias of January, the April NO3 performance is characterized by an underestimation bias (Figure C-11a). This under-prediction bias appears to be driven by near zero model predictions when the observed values are small (< 1 $\mu g/m^3$), but positive. This effect is especially noticeable in the NO3 time series (Figure C-11b) where at several sites the modeled NO3 concentrations foes to zero (e.g., BRET, BIBE, GUMO), whereas the observed values has an approximately 0.2 μg/m3 floor. The spatial maps suggest that the large April NO3 under-prediction bias indicated by the performance statistics is not as bad as they suggest (Figure C-11c). Mostly the model is predicting low NO3 values where low values are observed, just that the model approaches zero which results in a large relative difference with the observe values.

C.3.2.3 NO3 in July 2002

NO3 performance in July 2002 is also characterized by a large under-prediction bias that is driven by the frequent occurrence of near zero modeled values (Figure C-12). Both the model and observations agree that NO3 is mostly extremely low in July, just the model produces near zero values and resultant poor performance statistics.

C.3.2.4 NO3 in October 2002

Like January and unlike April and July, in October the model has a net NO3 overestimation bias of about 30%-40% (Figure C-13a). This overestimation bias occurs at all sites but BRET, BIBE and GUMO that exhibit a NO3 underestimation bias (Figure C-13b). The spatial maps suggest that the modeled elevated NO3 concentrations are more wide-spread and less spotty than observed.

C.3.2.5 NO3 Monthly Bias and Error

The monthly fractional bias values for NO3 clearly show the summer underestimation and winter overestimation bias (Figure C-14). The summer underestimation bias is more severe exceeding -100%, whereas the winter overestimation is closer to 50%. The fractional errors in the summer are also greater than in the winter with some values exceeding 100%. So based on statistics alone, it appears the summer underestimation bias is a bigger concern than the winter overestimation bias. However, the Bugle Plots in Figure C-15 paint a different picture entirely. The summer underestimation bias occurred when NO3 is low and is not an important component of PM and visibility impairment. These summer values occur in the flared horn part of the Bugle Plot and in fact the summer NO3 performance mostly achieves the model performance goal and always achieves the performance criteria. Whereas the winter overstated NO3 performance mostly doesn’t meet the performance goal and there are even some months/networks that don’t meet the performance criteria.

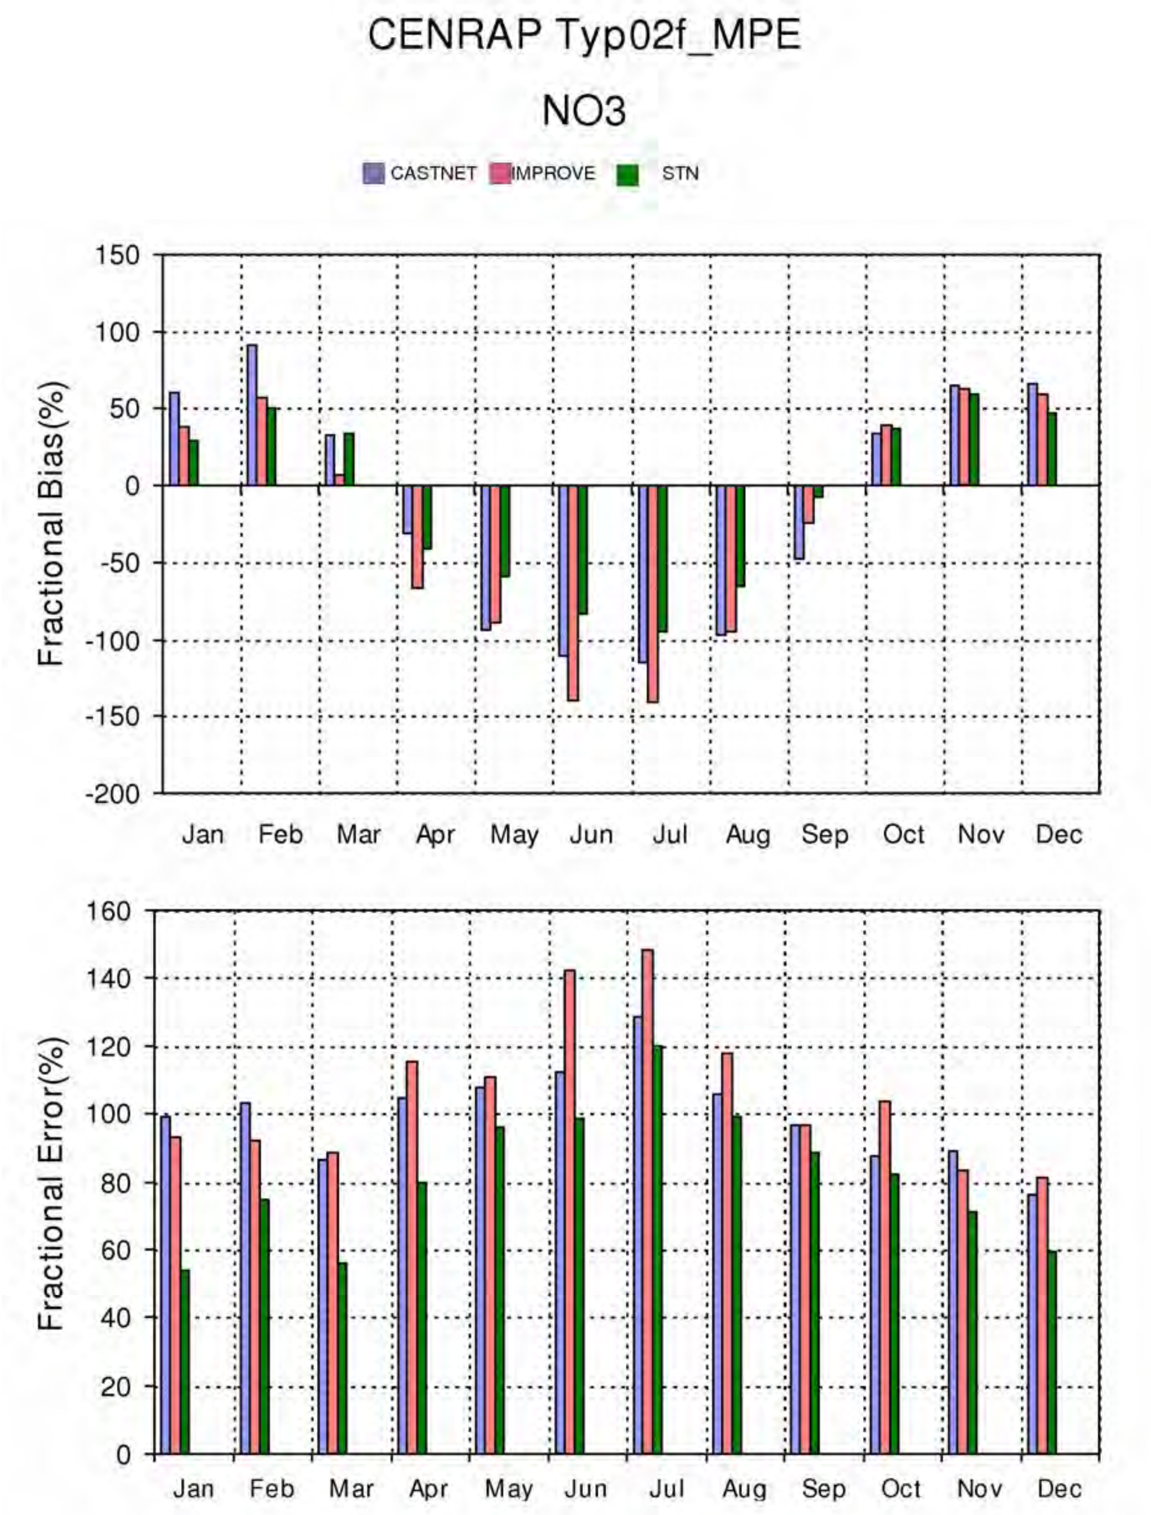

Figure C-14. Monthly NO3 fractional bias (top) and fractional gross error (bottom) statistical measures for IMPROVE, STN and CASTNet monitoring sites in the CENRAP region.

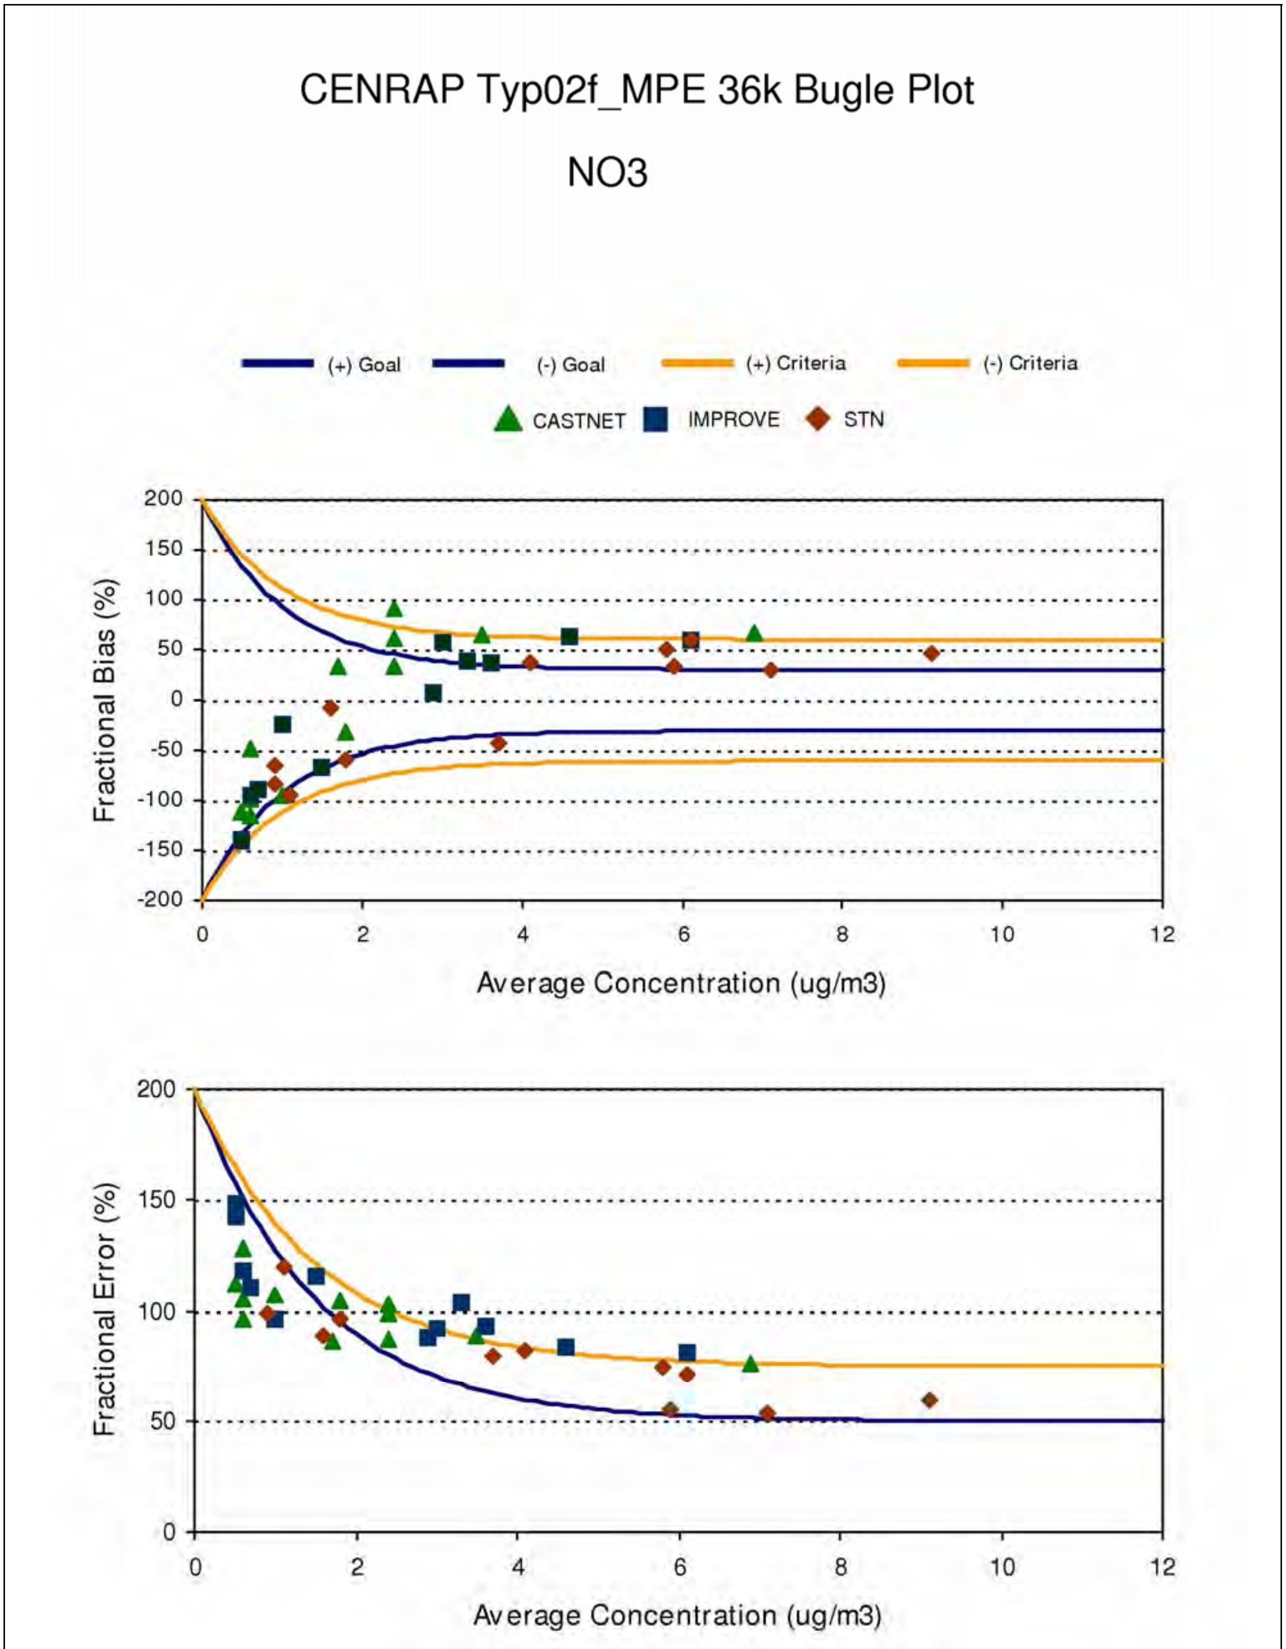

Figure C-15. Bugle Plots of monthly fractional bias (top) and fractional gross error (bottom) and comparisons with model performance goals and criteria for NO3 and IMPROVE, STN and CASTNet monitoring sites in the CENRAP region.

C.3.3 Organic Matter Carbon (OMC) Monthly Model Performance

Organic Matter Carbon (OMC) model performance is presented below. There is incommensurability between the observed and modeled OMC, the model provides estimates of OMC that includes Organic Carbon (OC) as well as other elements attached to the OC (e.g., oxygen), whereas the monitoring networks measure just the carbon component of OMC (i.e., OC). Consequently, the measured OC must be adjusted to OMC for comparison with the model to account for the additional elements attached to the carbon. The OMC/OC ratio is not constant and depends in part on the age of the OMC with fresh OMC having lower OMC/OC ratios than aged OMC. The original IMPROVE equation used an OMC/OC ratio of 1.4 based mainly on urban-oriented measurements. The new IMPROVE equation uses an OMC/OC ratio of 1.8 reflecting the fact that OMC at the more rural IMPROVE monitors is more aged than urban OMC. Thus, selecting a single OMC/OC ratio for adjusting the measured OC to OMC for the model evaluation is somewhat problematic when we have both urban (STN) and rural (IMPPROVE) monitors. In addition, measured OC also has substantial uncertainty with different measurement techniques differing by as much as 50% (Solomon et al., 2005). A 1.4 OMC/OC ratio was used to convert the measured OC to OMC for the model performance evaluation.

C.3.3.1 OMC in January 2002

Figure C-16a displays scatter plots and performance statistics for January OMC model performance across the IMPROVE and STN sites in the CENRAP region. OMC model performance is fairly with near zero bias across the IMPROVE sites, -38% underestimation bias across the STN sites and errors of ~50%. The underestimation of OMC at the urban STN sites is a common occurrence in air quality modeling and may indicate a missing source of urban OMC. With the exception of an underestimation bias at Breton Island and an over-prediction bias at the two Texas IMPORVE sites (BIBE and GUMO), the model reproduces the observed OMC time series in January fairly well. The modeled spatial distribution of OMC is in general agreement with the observations although it sometimes captures the elevated values on some days (e.g., January 29, 2002 in central Illinois) and misses it on others (e.g., January 26, 2002 at Mingo).

Figure C-16c. Spatial plot comparisons of the predicted and IMPROVE observed 24-hour OMC concentrations for January 20, 23, 26 and 29, 2002.

C.3.3.2 OMC in April 2002

The OMC performance in April is also fairly reasonable, again bias across the IMPROVE monitors is near zero (-7%), an underestimation bias exists across the STN sites (-30%) and errors are near 50% (Figure C-17a). The time series comparisons (Figure C-17b) are also reasonable with the model generally agreeing on the magnitudes of the observed OMC, but with an underestimation bias at several sites (e.g., MING and WIMO). The observed spatial distribution of OMCV appears to be much spottier than predicted (Figure C-17c). Thus, when the model reproduces an elevated observed OMC value like at UPBU on April 5th, it overestimates OMC at neighboring sites that have lower values (e.g., HEGL).

C.3.3.3 OMC in July 2002

Modeled and observed OMC are higher in July due to the impacts of more secondary organic aerosols (SOA) and fires. OMC bias values of -18% and -41% exist across the IMPROVE and STN networks in July (Figure C-18a). Two of the observed OMC values at the IMPROVE sites are very high (> 15 $\mu g/m^3$). An examination of the time series plots (Figure C-18b) reveals that these two values occur on Julian Day 200 and the two northern Minnesota sites (VOYA and BOWA) and are likely due to fire impacts. The model is also estimating elevated OMC at these sites on these two days, but not as high as observed. At most sites the model is racking the temporal variation of the observed OMC reasonably well. OMC data for MING were missing in July 2002. The model reproduces the observed high OMC in northern Minnesota and centered on Louisiana and adjacent areas on July 7 and 10 quite well, but also predicts elevated OMC in the Denver area that is not reflected in the observations (Figure C-18c). The model is exhibiting less skill in predicting the spatial distribution of the observed OMC on July 13 and 16.

C.3.3.4 OMC in October 2002

OMC model performance in October 2002 is similar to the other months with near zero bias across the IMPROVE sites and an underestimation bias across the STN sites in the CENRAP region (Figure C-19a). Although OMC overestimation bias occurs at the Texas sites (BIBE and GUMO), the model is exhibiting remarkable ability to reproduce the observed temporal variation in OMC at several of the sites (e.g., CACR, UPBU, VOYA and HEGL; Figure C-19b). The model also performs reasonable well in reproducing the day to day and spatial variability in the observed OMC (Figure C-19c).

C.3.3.5 OMC Monthly Bias and Error

The OMC monthly bias and error across IMPROVE and STN sites in the CENRAP region are shown in Figure C-20. The bias performance for OMC at the IMPROVE sites are quite good throughout the year with values generally within ±20%, albeit with a slight winter overestimation and summer underestimation bias. At the urban STN sites the model exhibits an underestimation bias throughout the year that ranges from -20% to -50%. Fractional errors are mostly within 40% to 60% with the STN network generally exhibiting more error than IMPROVE.

The good performance of the model for OMC at the IMPROVE sites is also reflected in the Bugle Plot (Figure C-21) with the bias and error achieving the proposed PM model performance goal for all months of the year. At the STN sites, however, the OMC bias falls between the proposed PM model performance goal and criteria, with error right at the goal for most months.

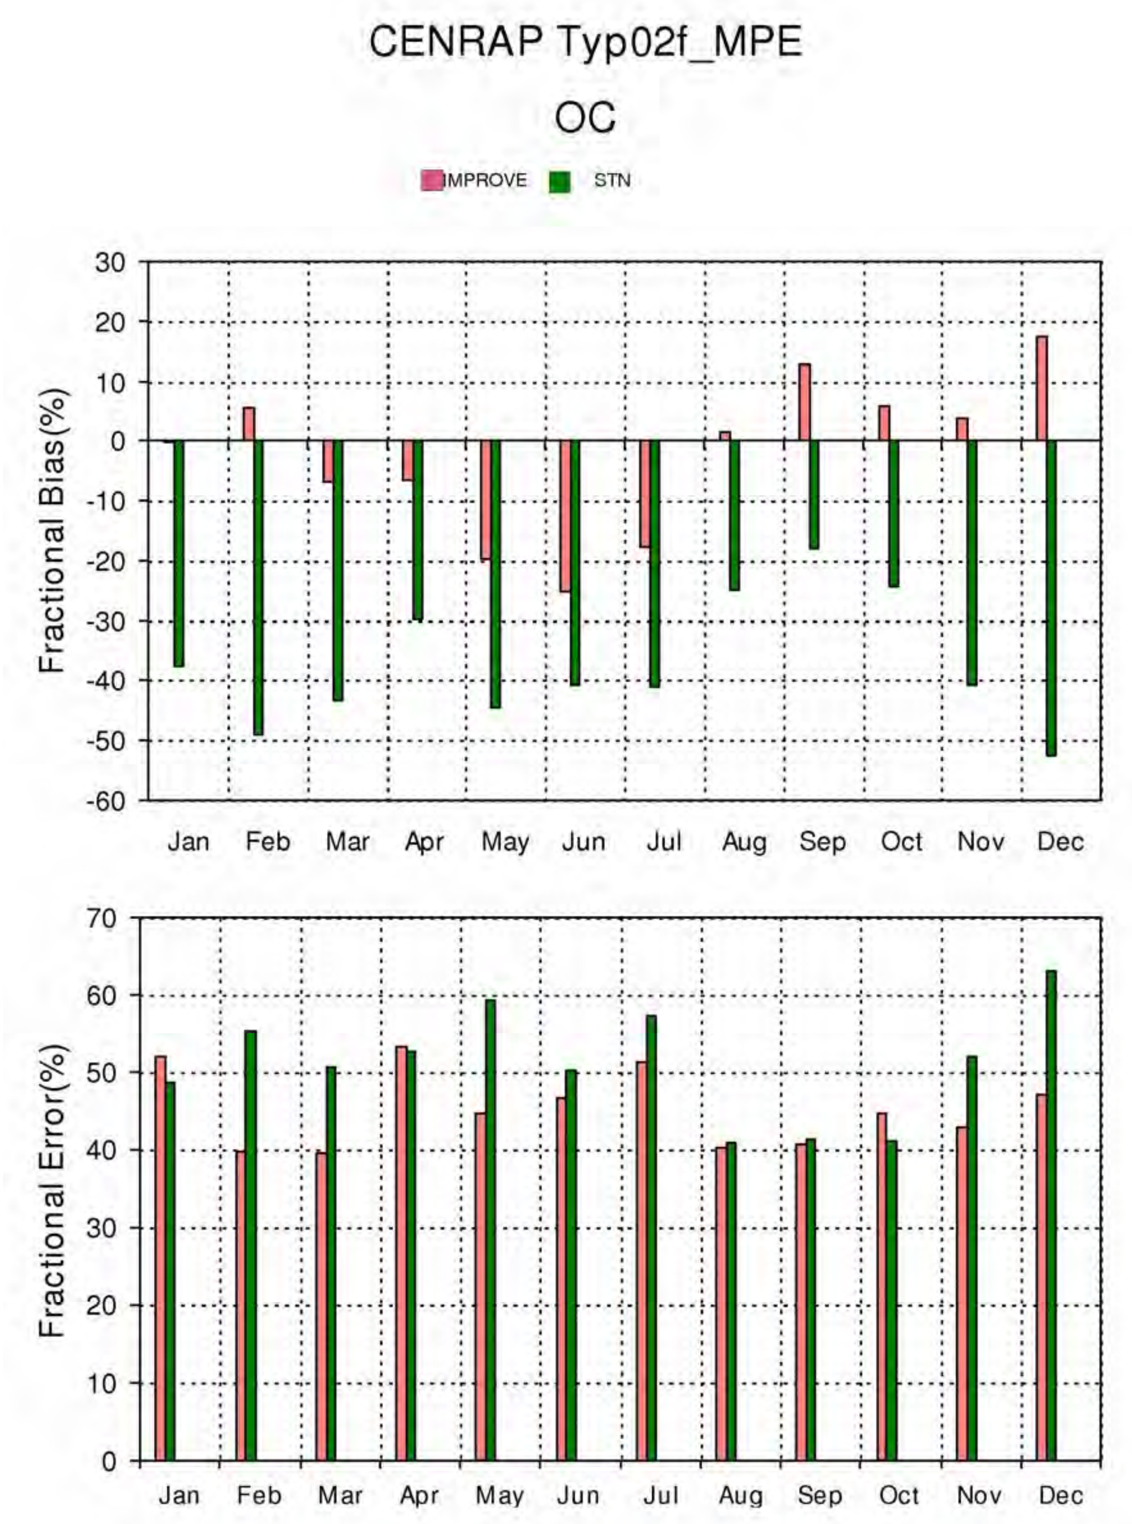

Figure C-20. Monthly OMC fractional bias (top) and fractional gross error (bottom) statistical measures for IMPROVE and STN monitoring sites in the CENRAP region.

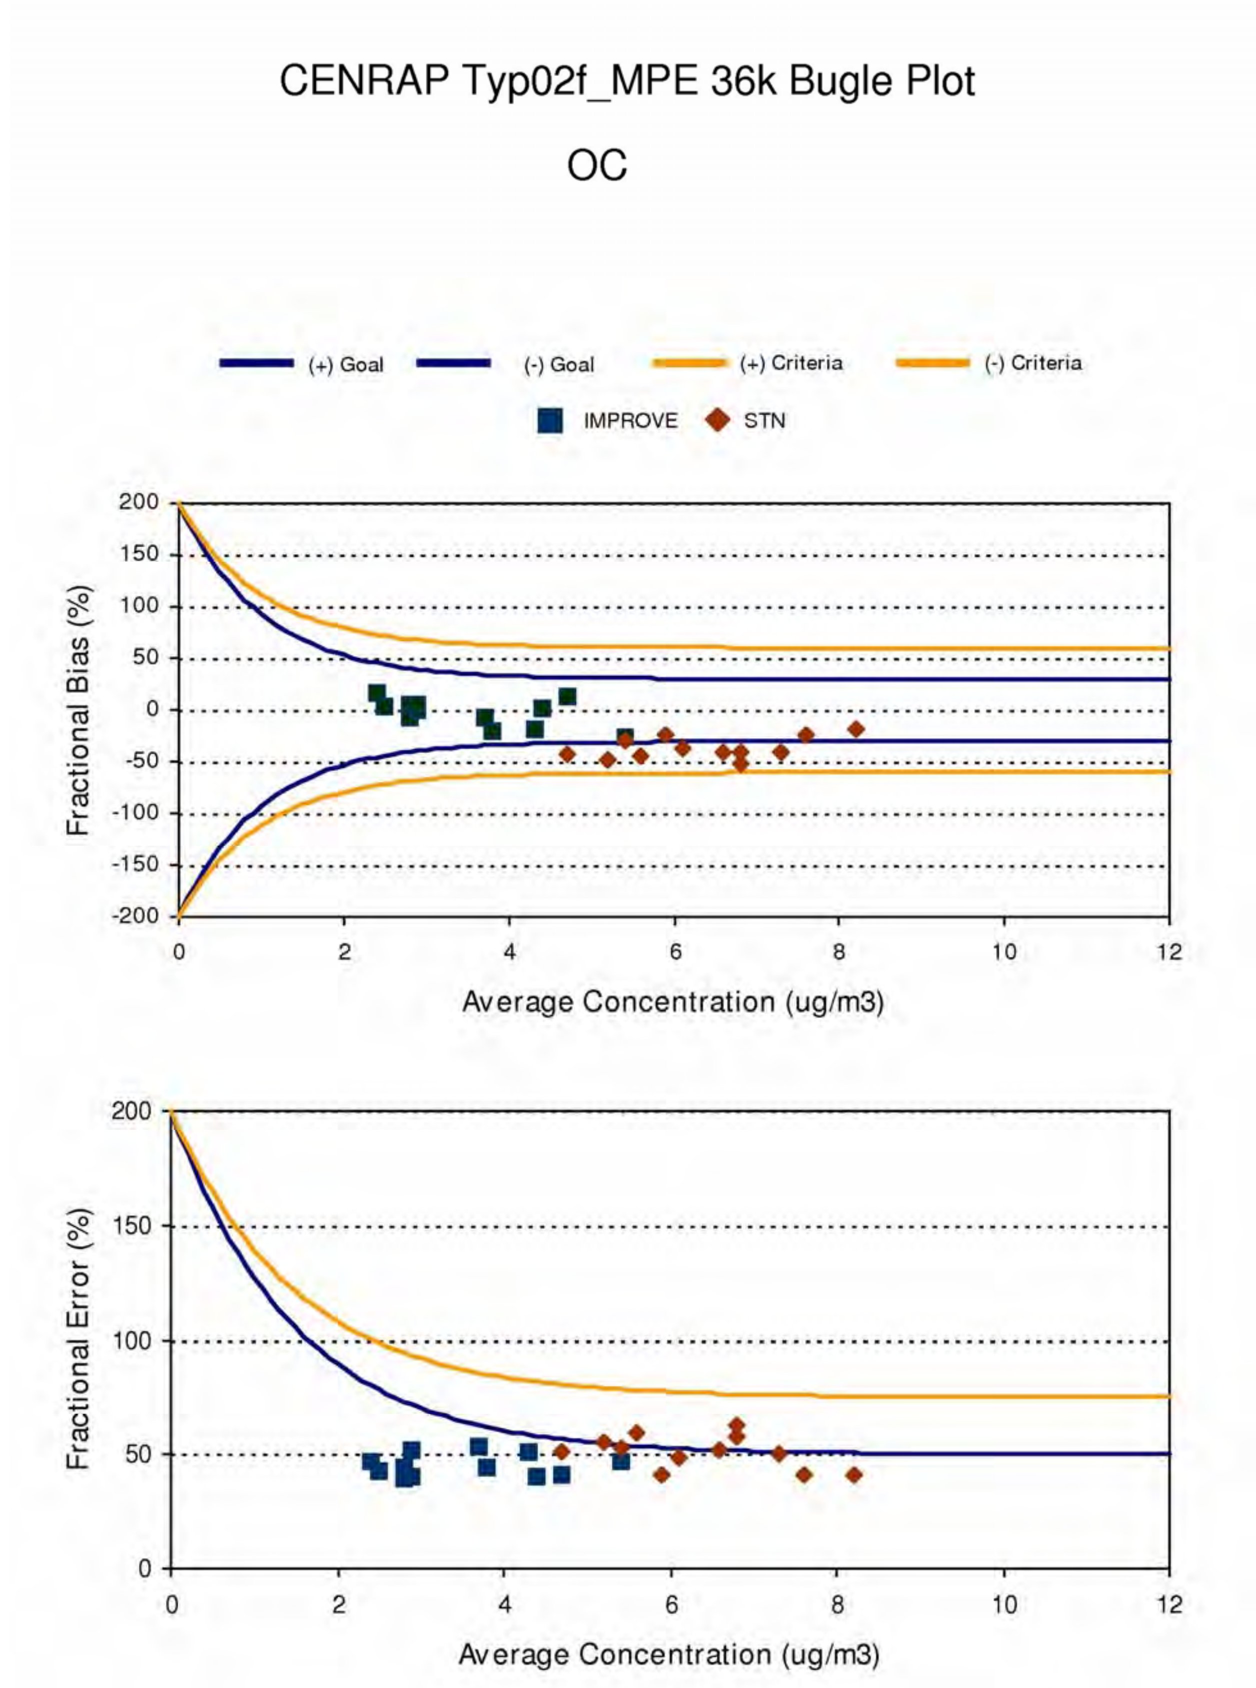

Figure C-21. Bugle Plots of monthly fractional bias (top) and fractional gross error (bottom) and comparisons with model performance goals and criteria for OMC and IMPROVE and STN monitoring sites in the CENRAP region.

C.3.4 Elemental Carbon (EC) Monthly Model Performance

Elemental Carbon (EC) measurements are also uncertain, with the IMPROVE and STN using different measurement technologies with different measurement artifacts.

C.3.4.1 EC in January 2002

Although there is a lot of scatter in the January EC scatter plots at the IMPROVE and STN sites, the bias is fairly low (-24% and 1%) with errors in the 40%-50% range (Figure C-22a). The time series comparisons (Figure C-22b) suggest an EC underestimation bias at BRET and an overestimation bias at the northern Minnesota sites (VOYA and BOWA). The model generally agrees with the observed spatial distribution of EC in January with higher values on the eastern than western portions of the CENRAP region (Figure C-22c).

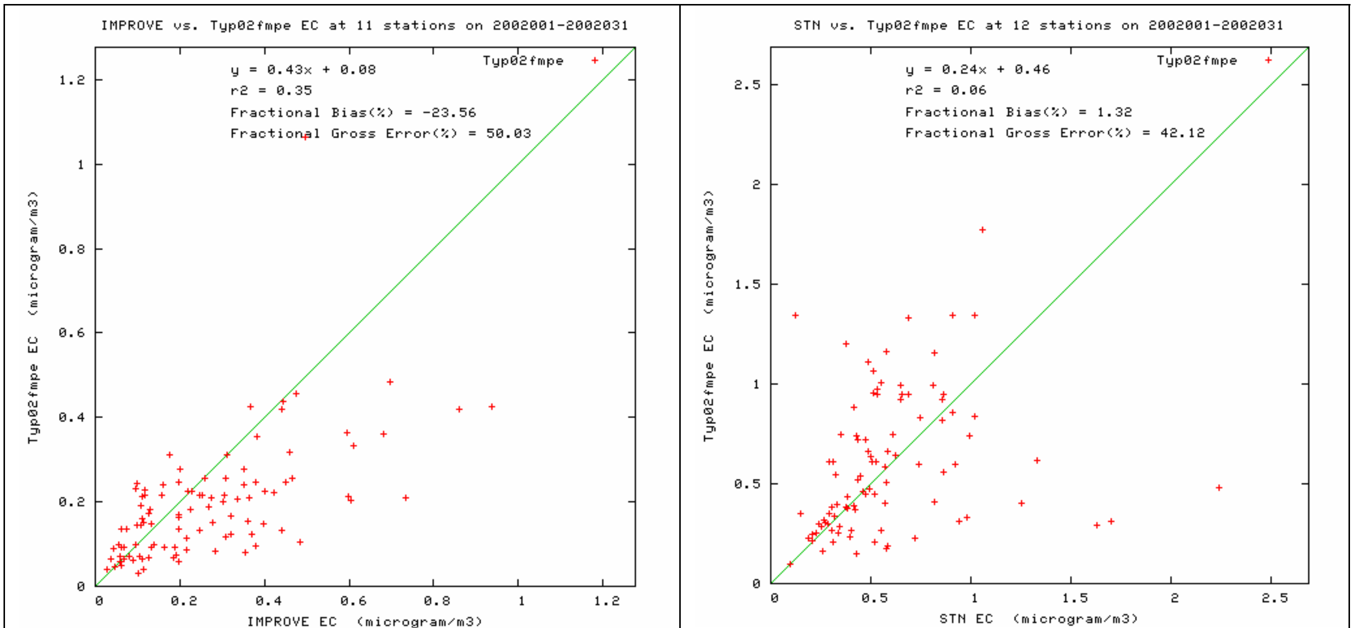

Figure C-22a. Scatter plots of predicted and observed elemental carbon (EC) concentrations for January 2002 and sites in the CENRAP region using IMPROVE (left) and STN (right) monitoring networks using the CMAQ 2002 36 km Base F base case simulation.

C.3.4.2 EC in April 2002

EC is underestimated at the IMPROVE sites in April (bias of -48%), but reproduced well at the STN sites (bias of -13%). Although EC is underestimated at the IMPROVE sites both the model and observations agree that EC concentrations are very small and not a significant component of the PM budget. The model fails to capture the day-to-day variability in the observed EC at the IMPROVE sites and exhibits a systematic under-prediction tendency at some sites (Figure C-23b). On April 5 and 11 the model reproduces the spatial distribution of the observed EC reasonable well with higher values in the eastern than western portion of the CENRAP region. But on April 8 and 14 the model is much to clean in the eastern portion of the CENRAP region (Figure C-23c).

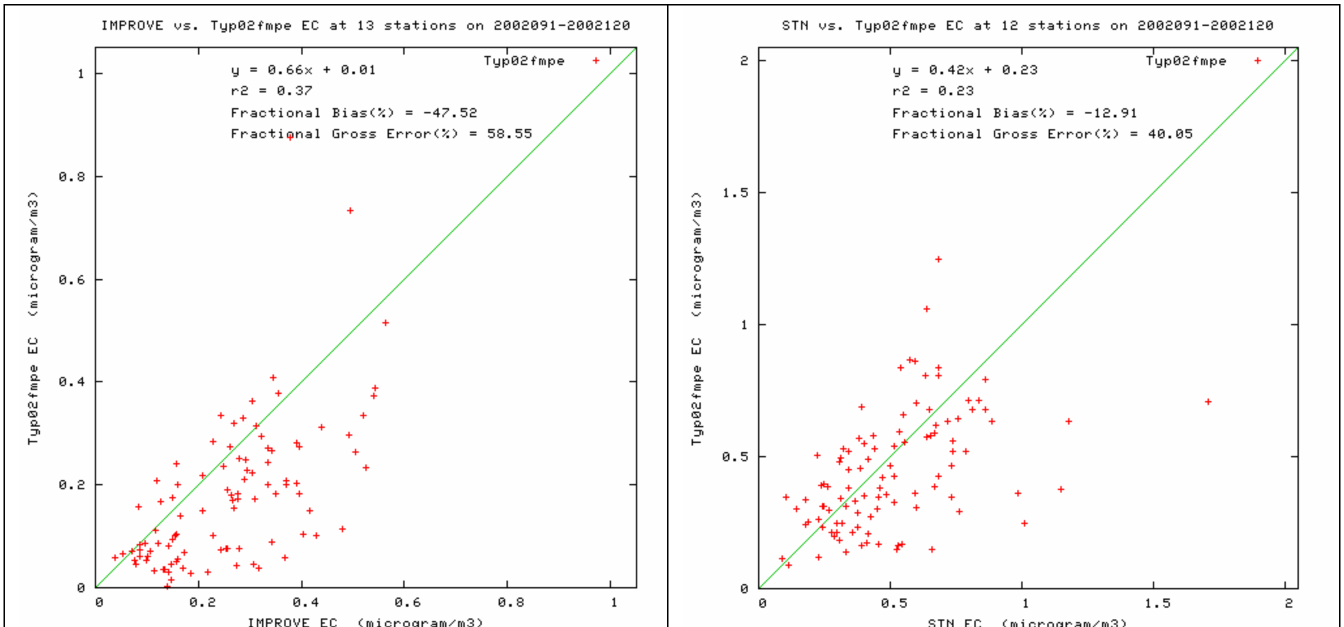

Figure C-23a. Scatter plots of predicted and observed elemental carbon (EC) concentrations for April 2002 and sites in the CENRAP region using IMPROVE (left) and STN (right) monitoring networks using the CMAQ 2002 36 km Base F base case simulation

Figure C-23c. Spatial plot comparisons of the predicted and IMPROVE observed 24-hour EC concentrations for April 5, 8, 11 and 14, 2002.

C.3.3.3 EC in July 2002

July EC performance is similar to the other months with near zero bias across he STN sites and an underestimation bias across the IMPROVE sites (Figure C-24). Again the model and observations agree that EC is low in July and not a significant component of visibility impairment.

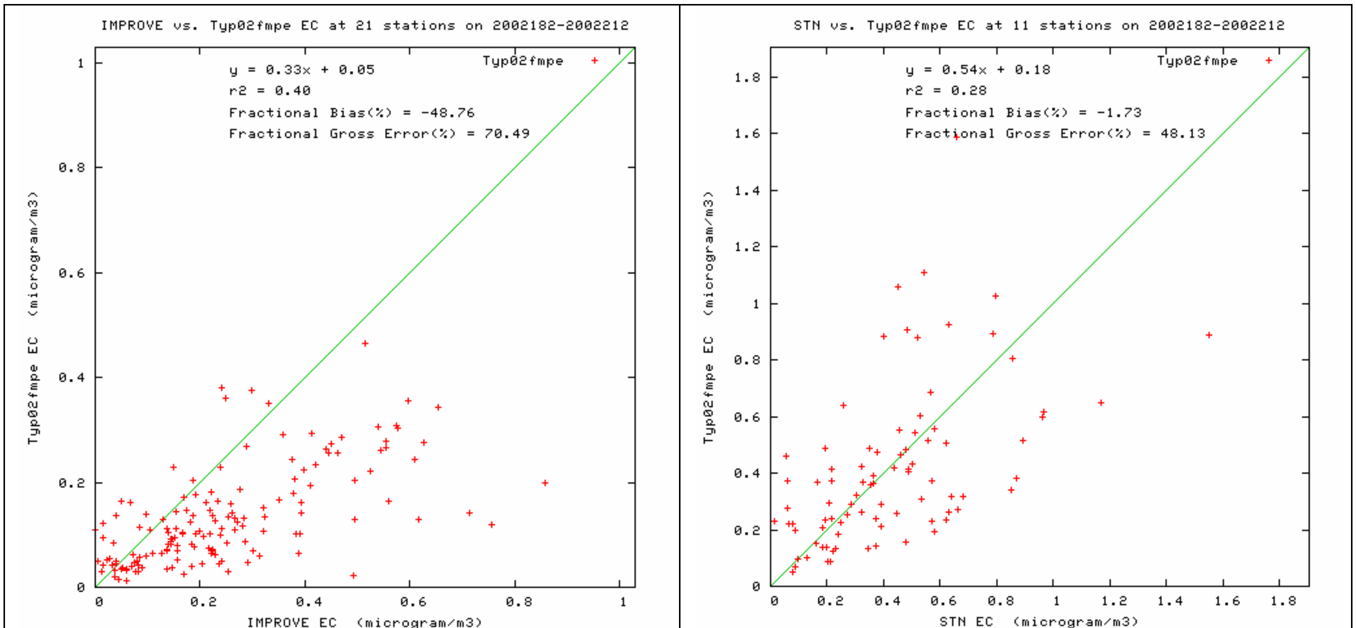

Figure C-24a. Scatter plots of predicted and observed elemental carbon (EC) concentrations for July 2002 and sites in the CENRAP region using IMPROVE (left) and STN (right) monitoring networks using the CMAQ 2002 36 km Base F base case simulation.

C.3.4.4 EC in October 2002

EC performance is improved at the IMPROVE sites in October with lower bias (9%) than the previous months where an under-prediction tendency was seen (Figure C-25a). EC bias is also fairly low at the STN sites with errors across both networks of approximately 50%. Although there is a systematic underestimation of EC at BRET, the agreement between the predicted and observed October time series (Figure C-25b) is remarkable at several sites (e.g., CACR, UPBU, VOYA and HEGL).

Figure C-25c. Spatial plot comparisons of the predicted and IMPROVE observed 24-hour EC concentrations for October 20, 23, 26 and 29, 2002.

C.3.4.5 EC Monthly Bias and Error

The monthly average bias and error for EC across the IMPROVE and STN monitors in the CENRAP region are shown in Figure C-26. The STN network exhibits low bias year round, whereas the IMPROVE monitoring network exhibits a large under-prediction bias in the summer months (-40% to -60%) and much lower EC bias in the winter. The errors in the IMPROVE summer EC performance are also quite high (60% to 80%), whereas during the winter the IMPROVE errors are in the 40% to 50% range which is also where the STN errors reside year round.

The Bugle Plot puts the EC performance in context (Figure C-27). The low EC concentrations put the IMPROVE EC performance in the horn of the Bugle Plot so that it achieves the proposed PM performance goal for all months of the year.

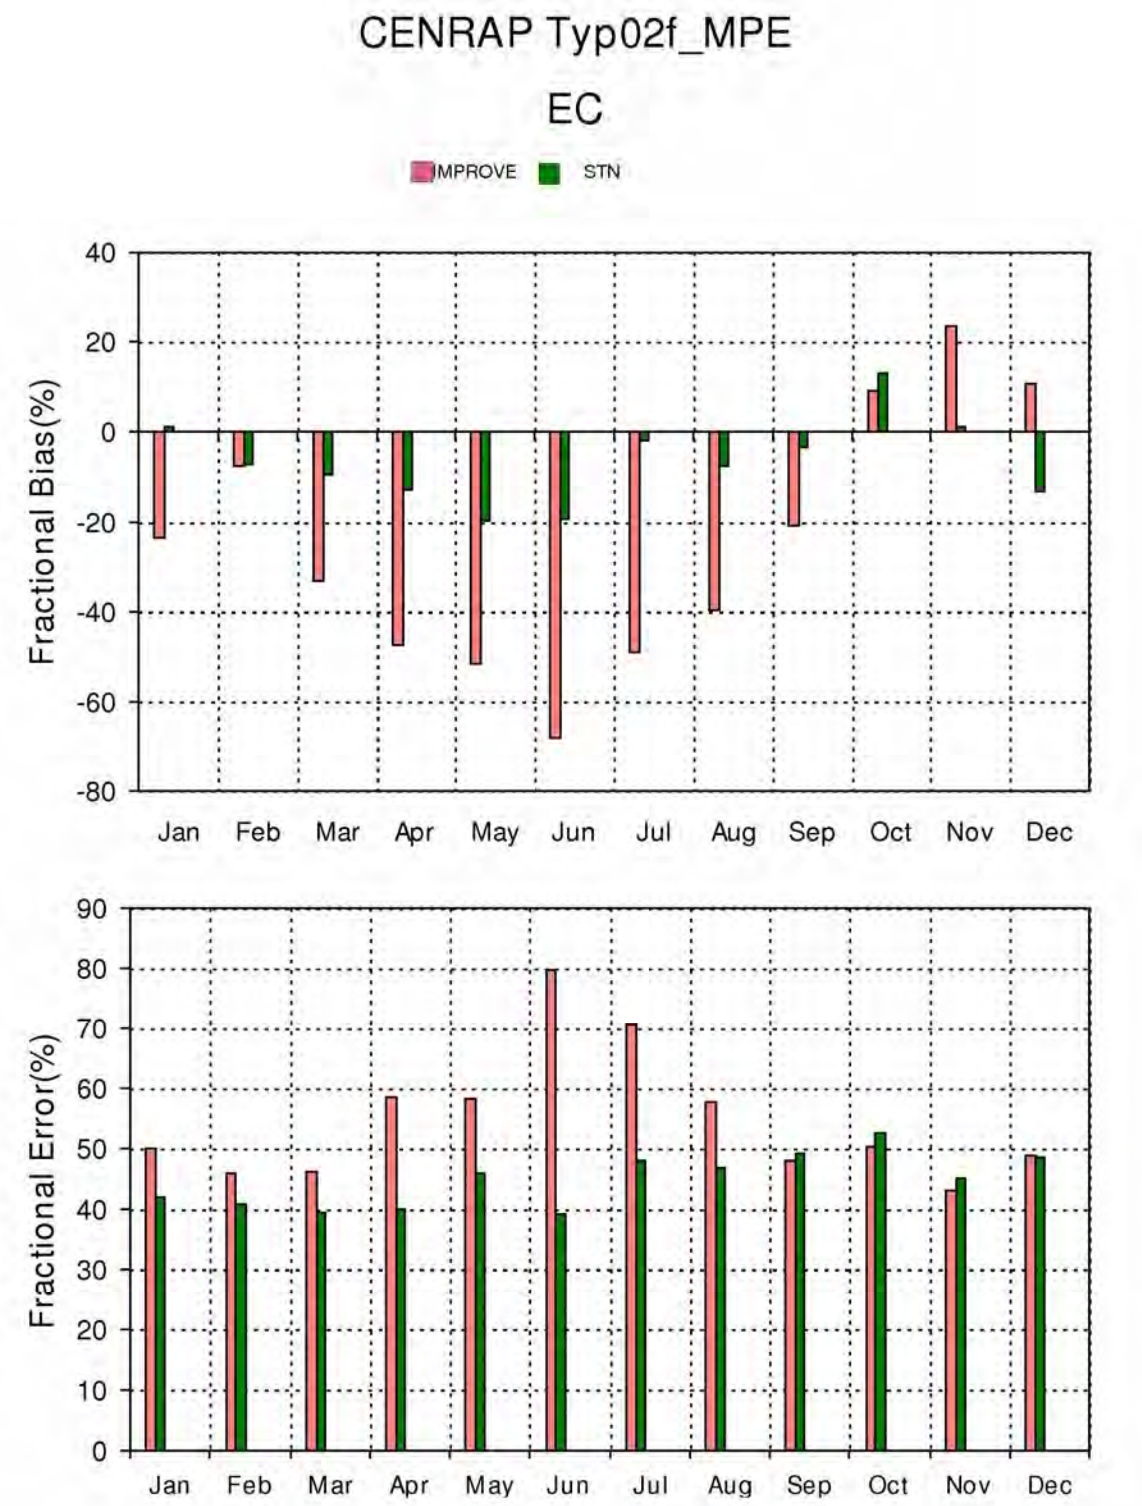

Figure C-26. Monthly EC fractional bias (top) and fractional gross error (bottom) statistical measures for IMPROVE and STN monitoring sites in the CENRAP region.

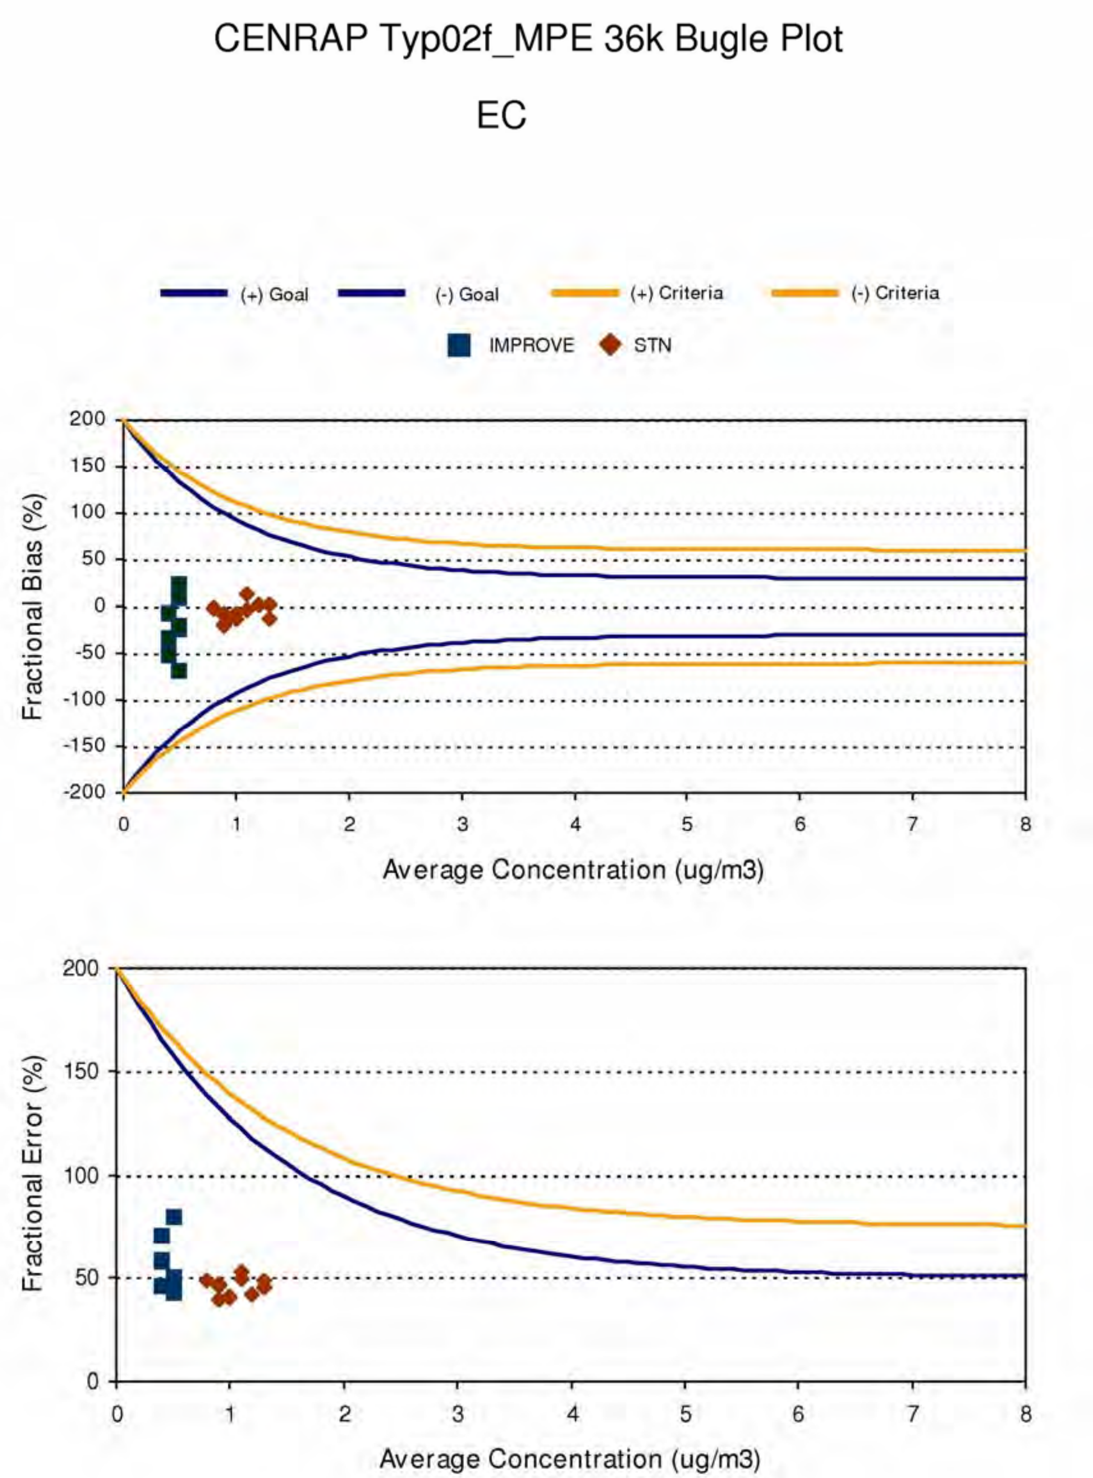

Figure C-27. Bugle Plots of monthly fractional bias (top) and fractional gross error (bottom) and comparisons with model performance goals and criteria for EC and IMPROVE and STN monitoring sites in the CENRAP region.

C.3.5 Other $PM_{2.5}$ (Soil) Monthly Model Performance

There are also model-measurement incommensurability problems with the other $PM_{2.5}$ (Soil) species. Whereas the IMPROVE Soil species is built up from measure elements, the modeled other $PM_{2.5}$ concentrations are based on emissions speciation profiles that likely include other species besides just elements. Soil is only collected at the IMPROVE monitors.

C.3.5.1 Soil in January 2002

The model greatly overestimates the Soil species at IMPORVE sites in January (Figure C-28a). The fractional bias exceeds 100% with errors of almost 130%. With the possible exception of the two Texas sites, the model Soil overestimation bias occurs across all of the CENRAP Class I areas in January (Figure C-28b). The model also does a poor job in reproducing the spatial variability of the observed Soil with a general overestimation tendency except at GUMO where it fails to reproduce the high Soil events.

C.3.5.2 Soil in April 2002

The model does a better job in reproducing the overall magnitude of the Soil measurements in April with a bias of 13% (Figure C-29a). But it exhibits little skill with lots of scatter and an error of 81%. The model is generally exhibiting a lot more day-to-day variability than observed with the observed daily time series much flatter than the modeled values (Figure C-29b). The modeled and observed spatial variability in Soil on April 5, 8, 11 and 14 are shown in Figure C-29c. Although the model exhibits large day-to-day variability, the observations do not reflect what the model predicts.

Figure C-29c. Spatial plot comparisons of the predicted and IMPROVE observed 24-hour Soil concentrations for April 5, 8, 11 and 14, 2002.

C.3.5.3 Soil in July 2002

The -50% Soil under-prediction bias seen in July appears to be driven to several high Soil measurements (Figure C-30a). An observed high Soil event took place on July 1 (Julian Day 182) across the Arkansas and Missouri Class I areas that all observed Soil values in excess of 15 $\mu g/m^3$. This event was not captured by the model. With the exception of a systematic Soil underestimation bias at the two Texas sites and missing these high Soil events, the model generally reproduces the magnitudes of the Soil observations in July.

C.3.5.4 Soil in October 2002

The nearly systematic Soil over-prediction bias seen in January returns in October (Figure C-31a). Except for the two Texas sites, BRET and BOWA, the model overstates the observed Soil during all days of October at the other monitoring sites (Figure C-31b). The model is predicting elevated Soil concentrations in the OK-KS-MO-IA area that is not reflected in the measurements (Figure C-31c).

C.3.5.5 Soil Monthly Bias and Error

Figure C-32 displays the monthly variation in the Soil bias and error. During the winter months the model exhibits a very large (> 100%) overestimation bias with large errors as well. With the exception of July, in the summer the model bias is a slight over-prediction but generally less than 20% with errors of 60% to 80%. The Bugle Plot indicates that the summer Soil performance achieves the PM performance goal, a few months in the Spring/Fall period fall between the performance goal and criteria and the winter Soil performance exceeds the model performance criteria by a far margin. Thus, the Soil performance is a cause for concern.

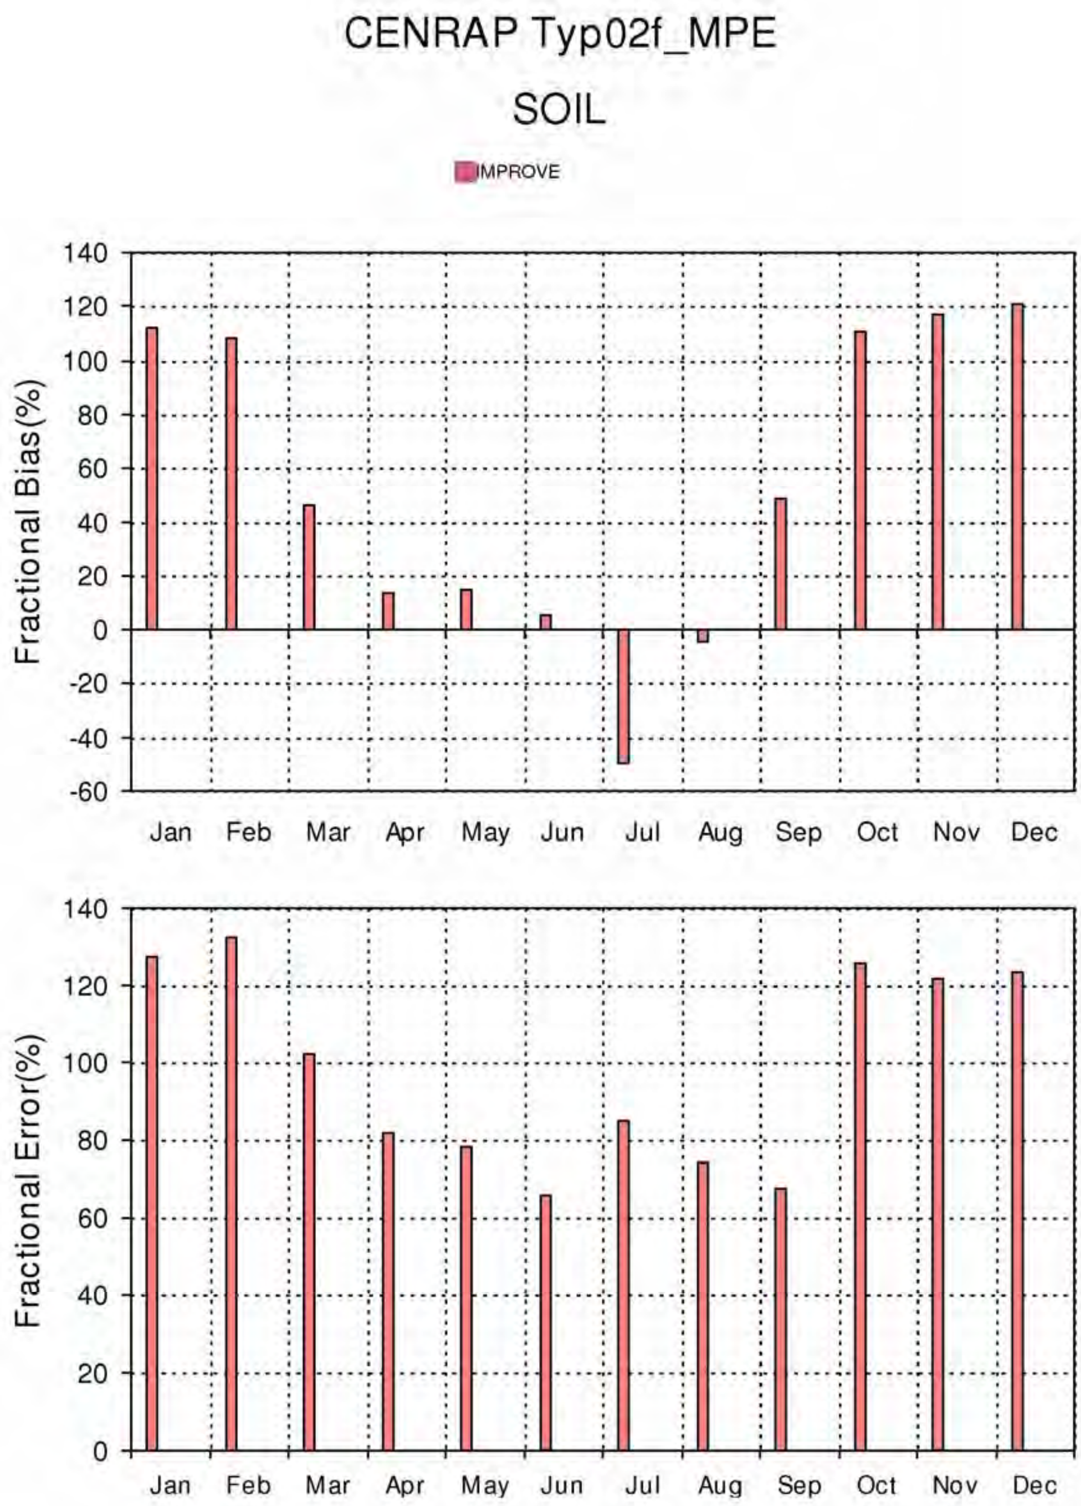

Figure C-32. Monthly Soil fractional bias (top) and fractional gross error (bottom) statistical measures for IMPROVE, STN and CASTNet monitoring sites in the CENRAP region.

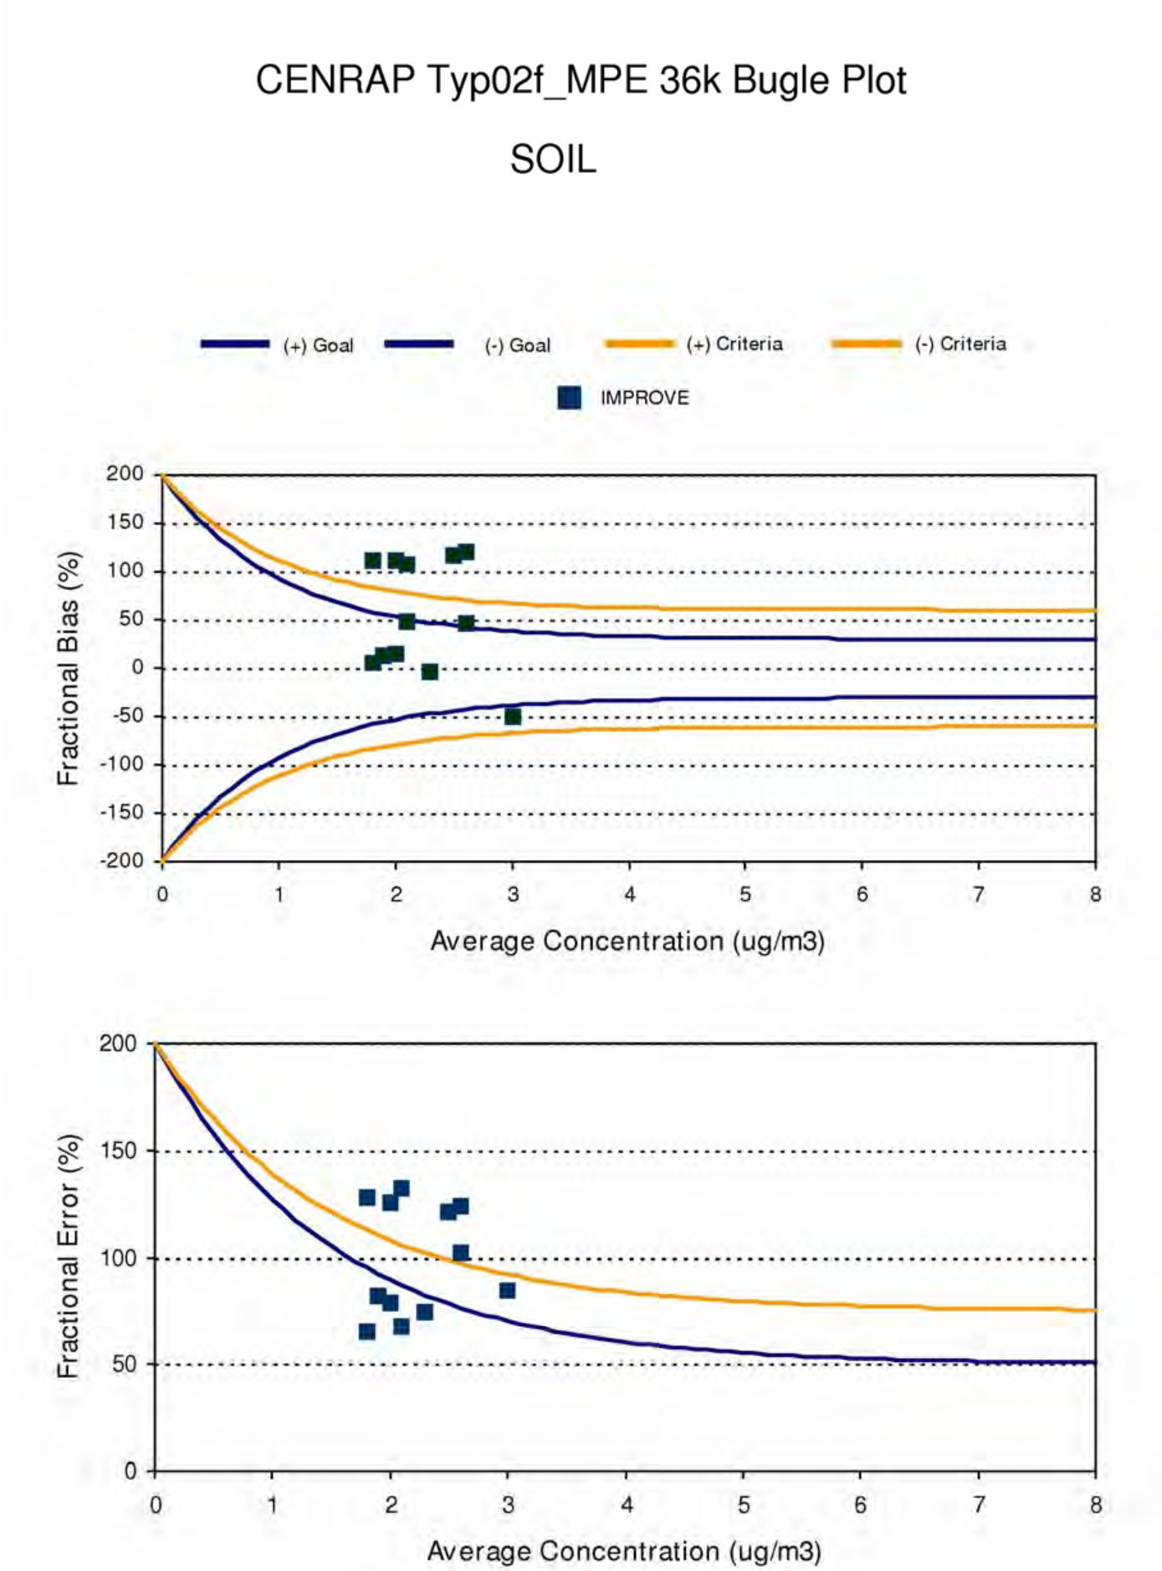

Figure C-33. Bugle Plots of monthly fractional bias (top) and fractional gross error (bottom) and comparisons with model performance goals and criteria for Soil and IMPROVE monitoring sites in the CENRAP region.

C.3.6 Coarse Mass (CM) Monthly Model Performance

The IMPROVE coarse mass (CM) measurement is taken as the difference between the PM_{10} and $PM_{2.5}$ mass measurement. Any SO4 or NO3 in the coarse mode will be in the CM measurement. The model, on the other hand, only includes primary CM. Any coarse SO4 or NO3 will be in the SO4 and NO3 modeled species.

C.3.6.1 CM in January 2002

The model underestimates the observed CM in January with a fractional bias of -83% (Figure C-34a). Although the model appears to reproduce CM at some sites (e.g., VOYA) at the two Texas sites the bias is approximately -150% (Figure C-34b). The observed spatial distribution of CM in January is not reproduced by the model at all (Figure C-34c). Whereas the observations indicate high CM concentrations in the west Texas-New Mexico area, the model estimates elevated CM in northeast Texas, through Oklahoma, Kansas, Iowa and into southern Minnesota. Although the CM measurements at WIMO in this area are also elevated, the rest of the high modeled CM values fall in between the IMPROVE monitors so can not be verified or refuted by the measurements.

C.3.6.5 CM Monthly Bias and Error

The monthly average fractional bias and error values for CM are shown in Figure C-38. In the winter the under-prediction bias is typically in the -60% to -80% range. In the late Spring and Summer the under-prediction bias ranges from -120% to -160%. As this under-prediction bias is nearly systematic, then the errors are the same magnitude as the bias.

The Bugle Plots clearly show that the CM model performance is a problem. The monthly bias exceeds both the performance goal and criteria for almost every month of the year. The error criteria are also exceeded for all months of the year.

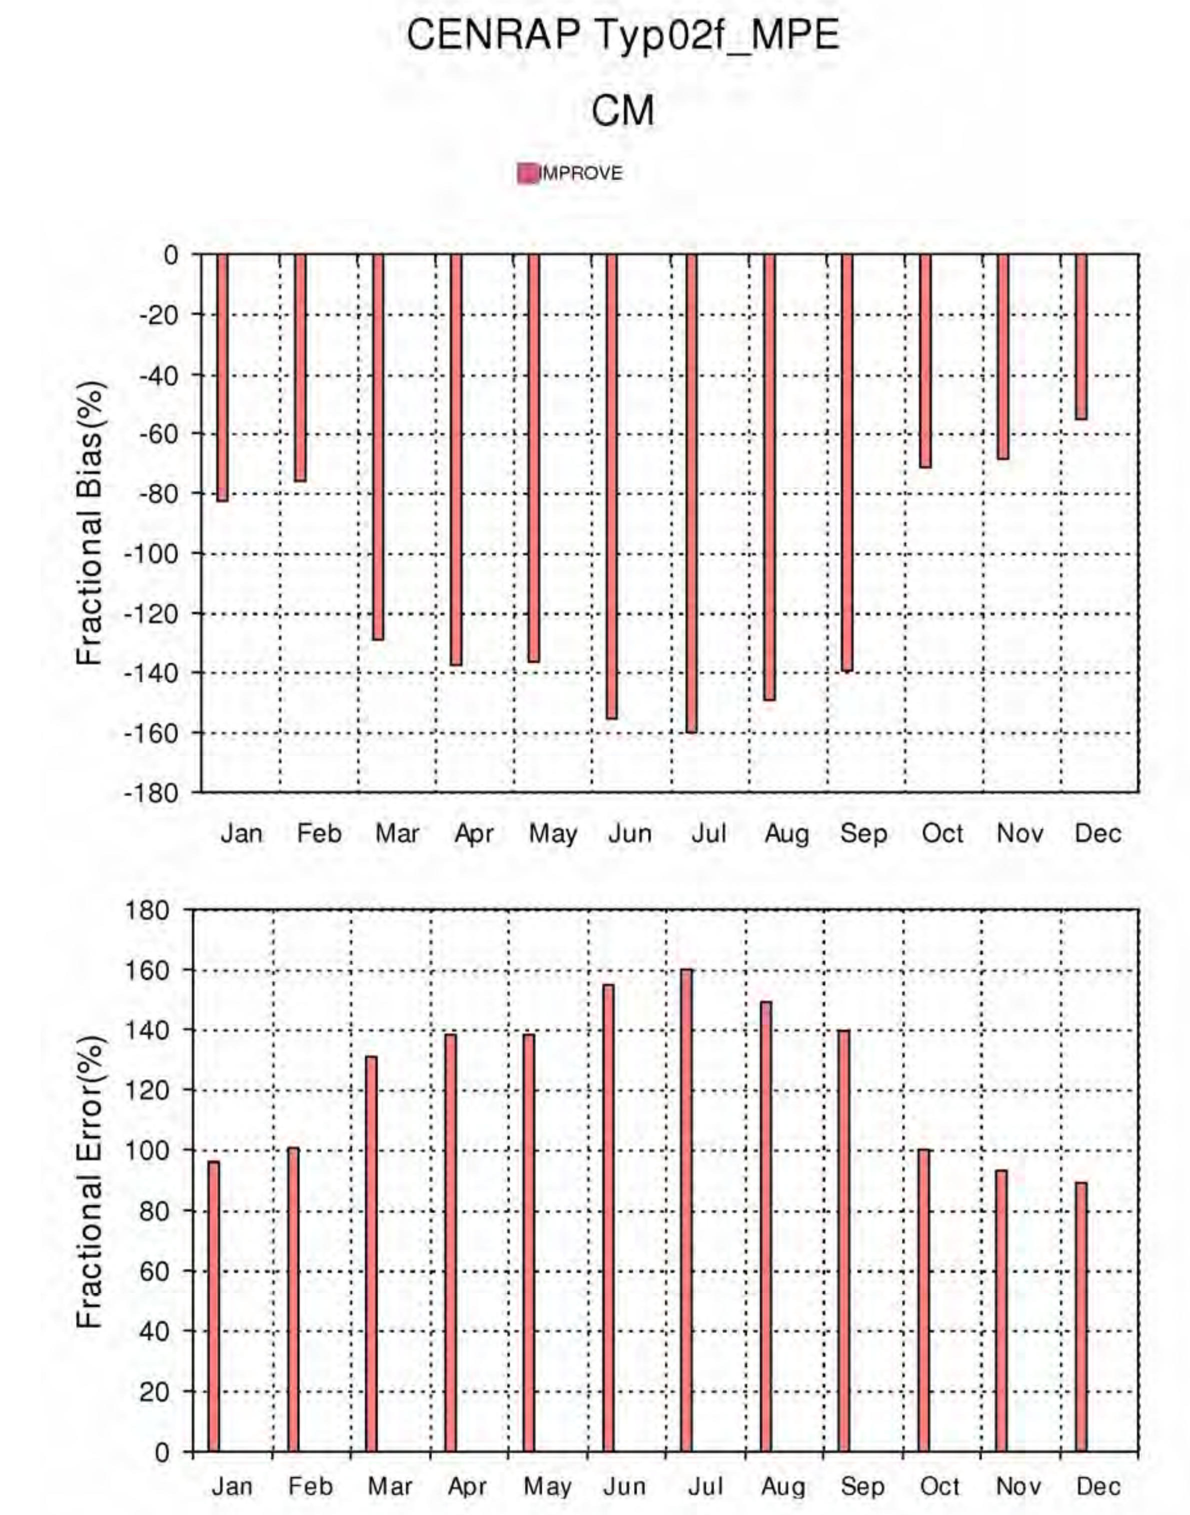

Figure C-38. Monthly CM fractional bias (top) and fractional gross error (bottom) statistical measures for IMPROVE monitoring sites in the CENRAP region.

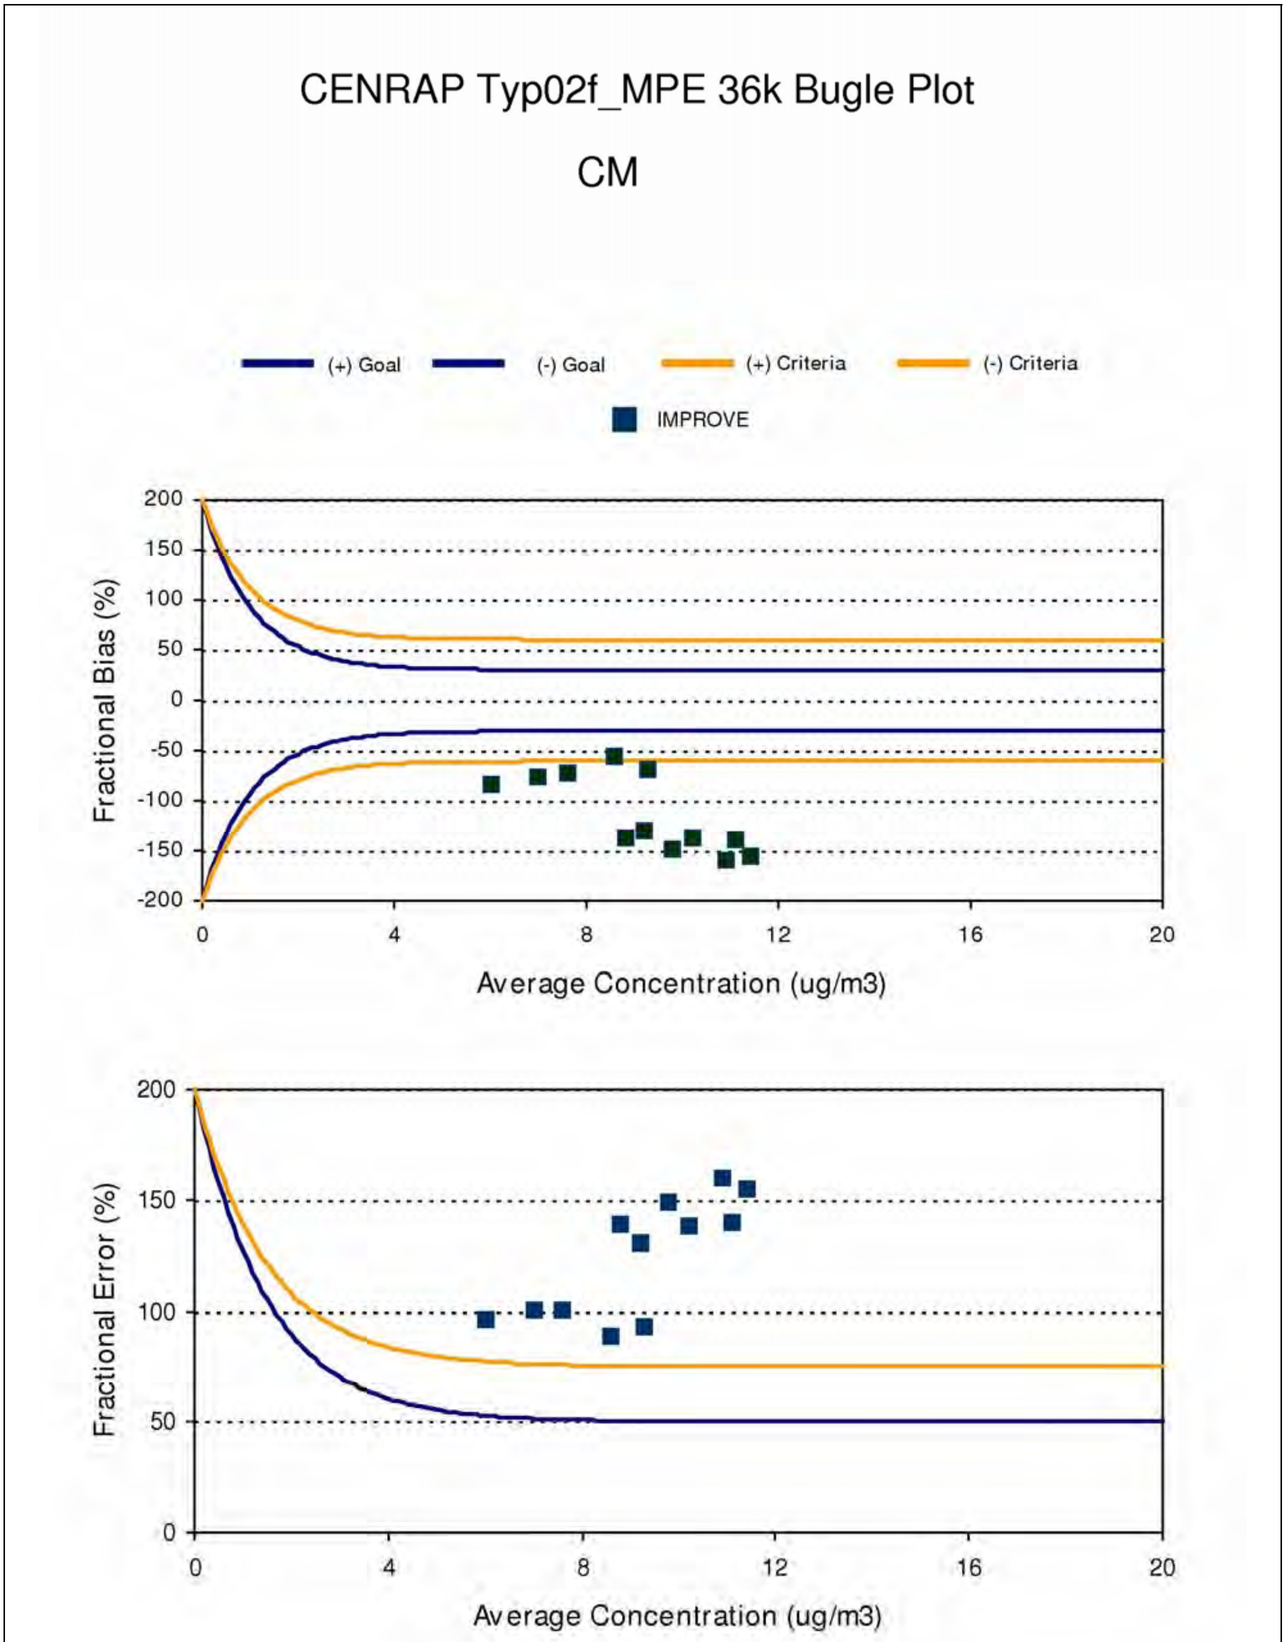

Figure C-39. Bugle Plots of monthly fractional bias (top) and fractional gross error (bottom) and comparisons with model performance goals and criteria for CM and IMPROVE monitoring sites in the CENRAP region.

C.4 Diagnostic Model Evaluation for Gas-Phase and Precursor Species

The CASTNet and AQS networks also measure gas-phase species that are PM precursor or related species. The diagnostic evaluation of the 2002 36 km Base F CMAQ base case simulation for these compounds and the four seasonal months presented previously is provided below.

The CASTNet network measures weekly average samples of SO2, SO4, NO2, HNO3, NO3 and NH4. The AQS network collects hourly measurements of SO2, NO2, O3 and CO. A comparison of the SO2 and SO4 performance provides insight into whether the SO4 formation rate may be too slow or fast. For example, if SO4 is underestimated and SO2 is overestimated that may indicate too slow chemical conversion rate. Analyzing the performance for SO4, HNO3, NO3, Total NO3 and NH4 provides insight into the equilibrium of these species. For example, if Total NO3 performs well but HNO3 and NO3 do not, then there may be issues associated with the partitioning between the gaseous and particle phases of nitrate.

C.4.1 Diagnostic Model Performance in January 2002

In January, SO2 is overstated across both the CASTNet and AQS sites with fractional bias values of 38% (Figure C-40) and 31% (Figure C-41), respectively. SO4 is understated by -34% across the CASTNet monitors (Figure C-40) and -12% and -13% for the IMPROVE and STN networks (Figure C-4a). As noted previously, wet SO4 deposition is also overstated in January (+40%, Figure C-4a). Given that SO2 emissions are well characterized, these results suggest that the January SO4 underestimation may be partly due to understated transformation rates of So2 to SO4 and overstated wet SO4 deposition.

Total NO3 is overestimated by 35% on average across the CASTNet sites in the CENRAP region in January (Figure C-40). HNO3 is underestimated (-34%) and particle NO3 is overestimated (+61%) suggesting there are gas/particle equilibrium issues. An analysis of the time series of the four CASTNet stations reveals that NO3, HNO3 and NH4 performance is actually very reasonable at the west Texas and the HNO3 underestimation and NO3 overestimation bias is coming from the east Kansas, central Arkansas and northern Minnesota CASTNet sites. One potential contributor for this performance problem is overstated NH3 emissions. However the overstated Total NO3 suggests that the model estimated NOx oxidation rate may be too high in January.

The SO2, NO2, O3 and CO performance across the AQS sites in January is shown in Figure C-41. The AQS monitoring network is primarily an urban-oriented network so it is not surprising that the model is underestimating concentrations of primary emissions like NO2 (-5%) and particularly CO (-67%) when a 36 km grid is used. Ozone is also underestimated on average, especially the maximum values above 60 ppb.

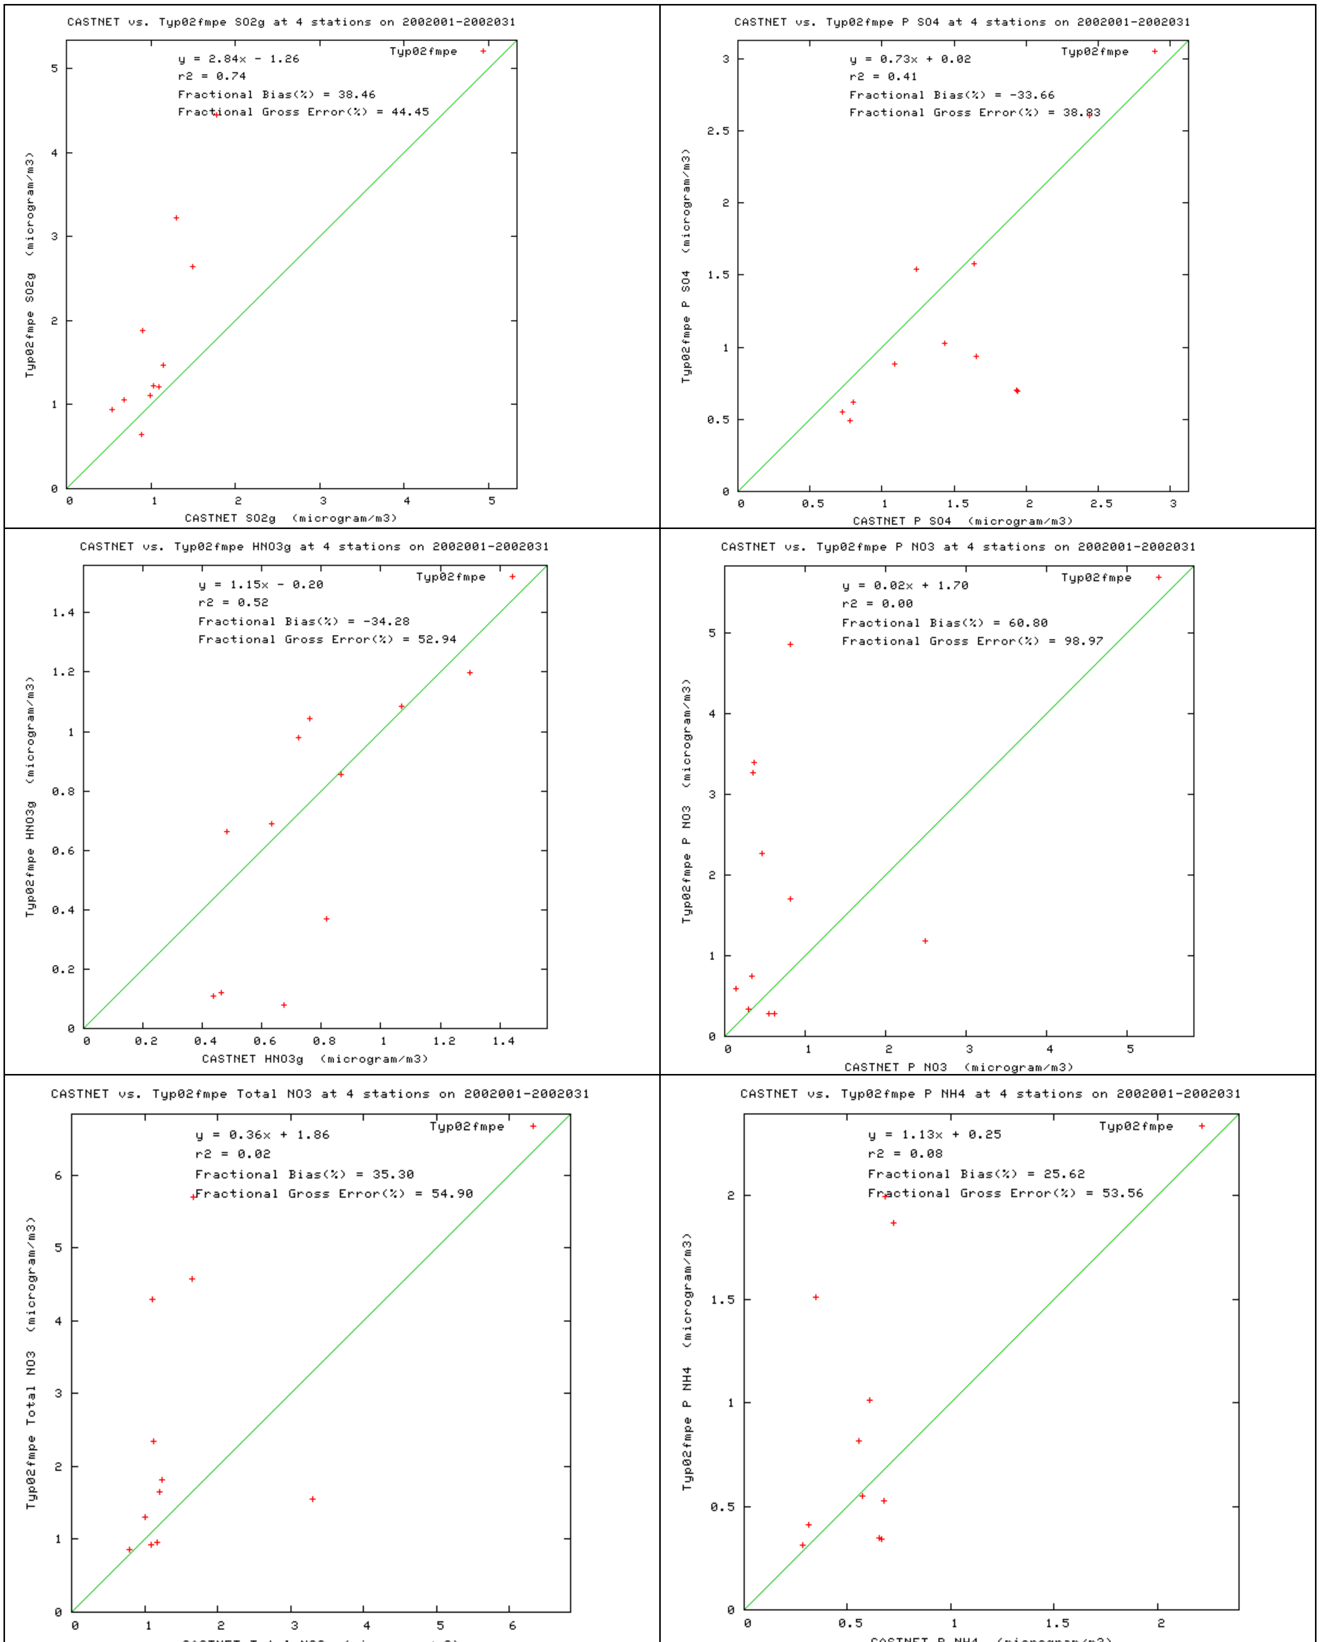

Figure C-40. January 2002 performance at CENRAP CASTNet sites for SO2 (top left), SO4 (top right), HNO3 (middle left), NO3 (middle right), Ttoal NO3 (bottom left) and NH4 (bottom right).

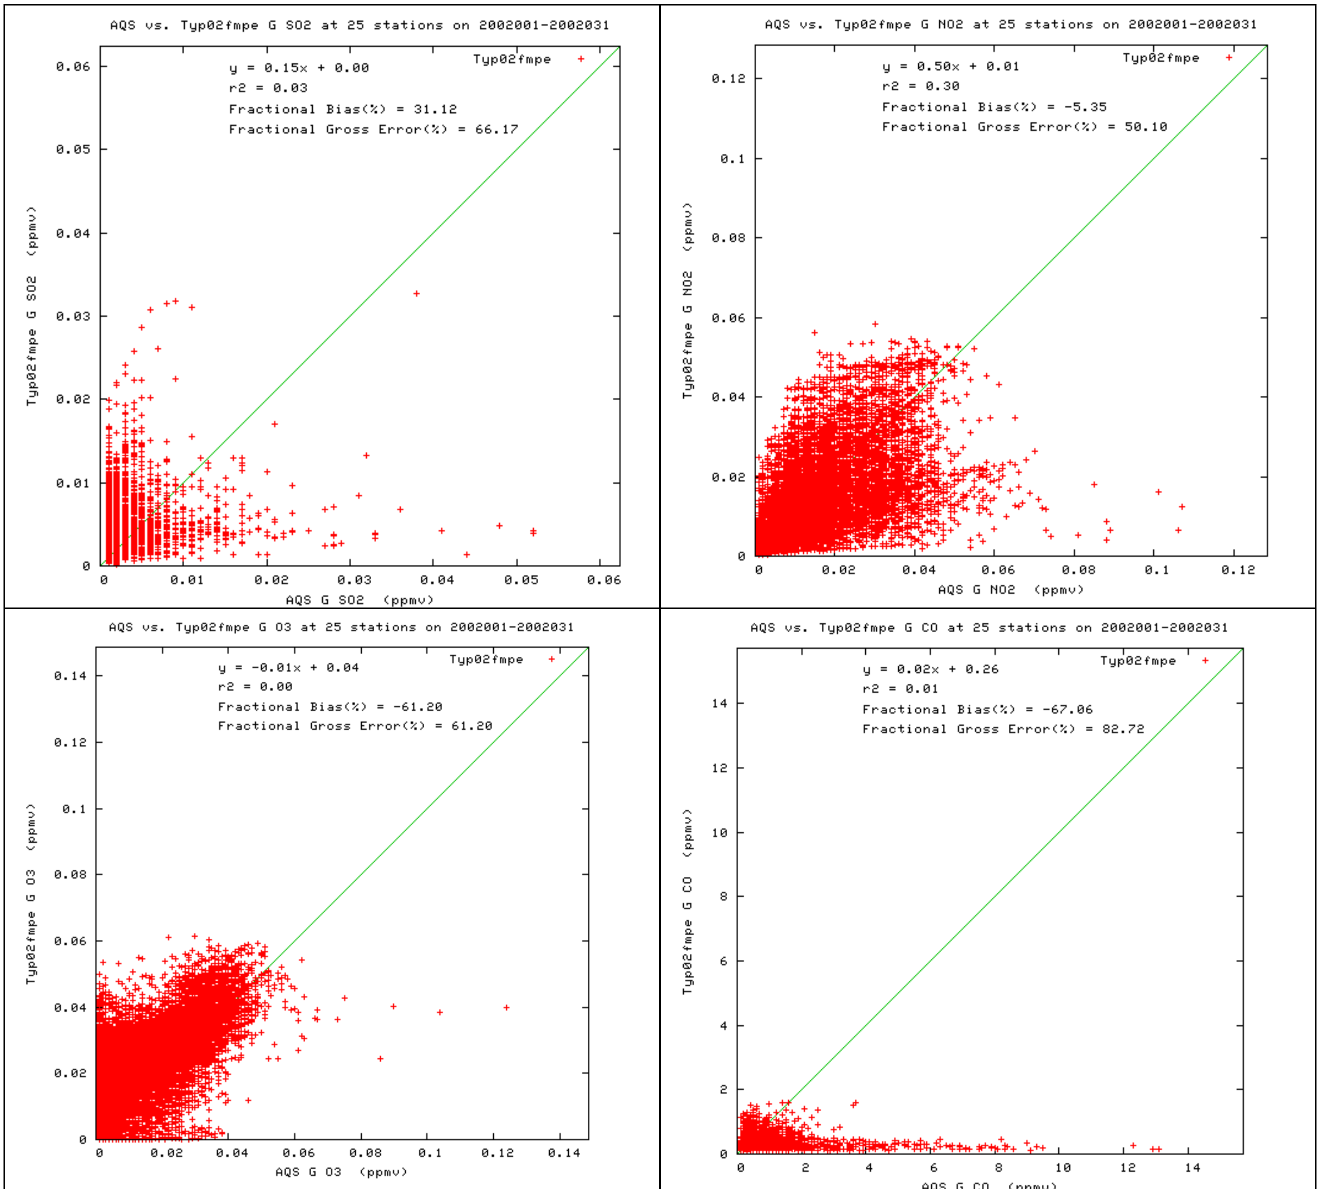

Figure C-41. January 2002 performance at CENRAP AQS sites for SO2 (top left), NO2 (top right), O3 (bottom left) and CO (bottom right).

C.4.2 Diagnostic Model Performance In April

In April there is an average SO2 overestimation bias across the CASTNet (+15%) and underestimation bias across the AQS (-10%) networks (Figures C-42 and C-43). SO4 is underestimated across all networks by -30% to -58% (Figure C-5a). The wet SO4 deposition bias is near zero. Both SO2 and SO4 are underestimated at the west Texas CASTNet monitor in April suggesting SO2 emissions in Mexico are likely understated.

The HNO3 performance in April is interesting with almost perfect agreement except for 5 modeled-observed comparisons that drives the average under-prediction bias of -29%. On Julian Day 102 there is high HNO3 at the MN, KS and OK CASTNet sites that is not captured by the model. Given that HNO3, NO3 and Total NO3 are all underestimated by about the same amount (-30%), then part of the underestimation bias is likely due to too slow oxidation of NOx.

There is a lot of scatter in the NO2 and O3 performance that is more or less centered on the 1:1 line of perfect agreement with bias values of -8% and -21%, respectively (Figure C-43). CO is underestimated by -72% with the model unable to predict CO concentrations above 1 $\mu g/m^3$ due to the use of the coarse 36 km grid spacing. Mobile sources produce a vast majority of the CO emissions so AQS monitors for CO compliance are located near roadways, which are not simulated well using a 36 km grid.

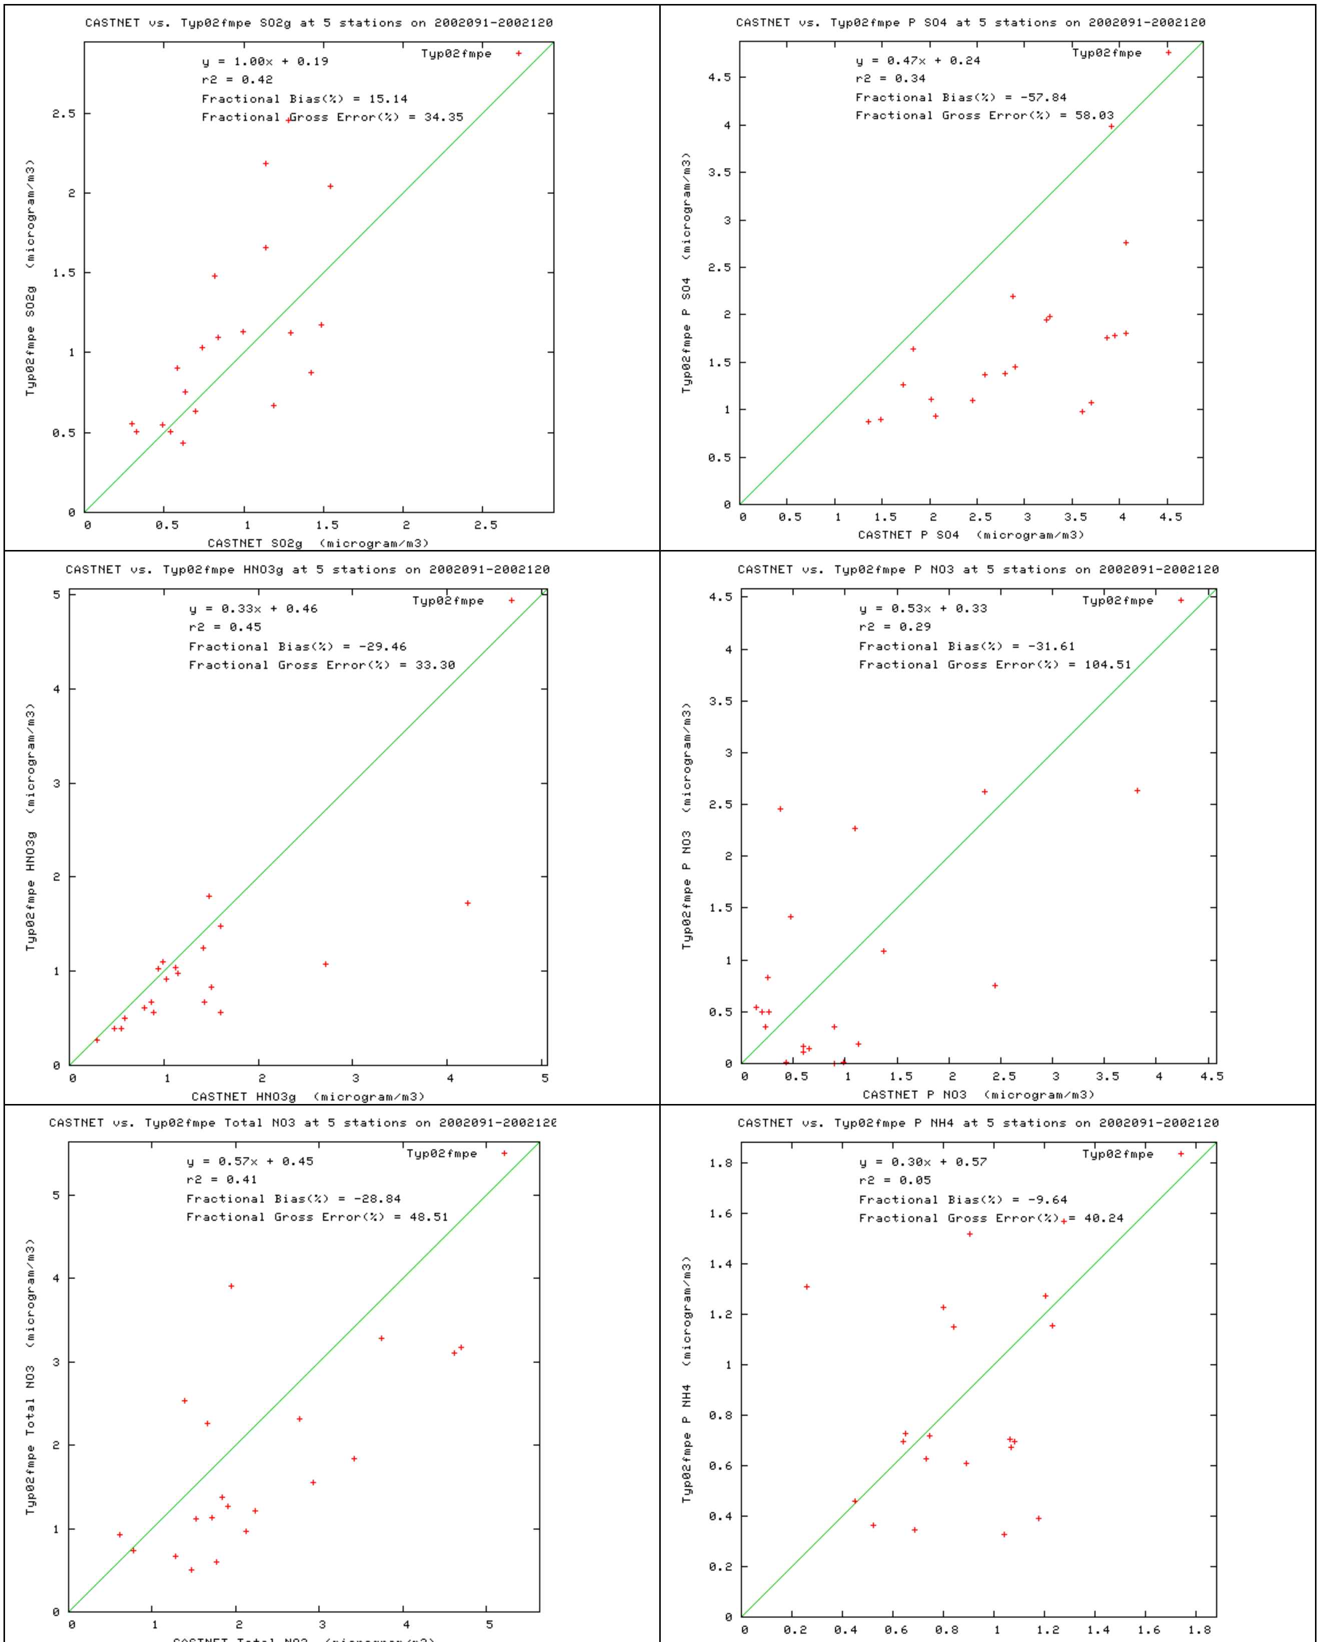

Figure C-42 April 2002 performance at CENRAP CASTNet sites for SO2 (top left), SO4 (top right), HNO3 (middle left), NO3 (middle right), Total NO3 (bottom left) and NH4 (bottom right).

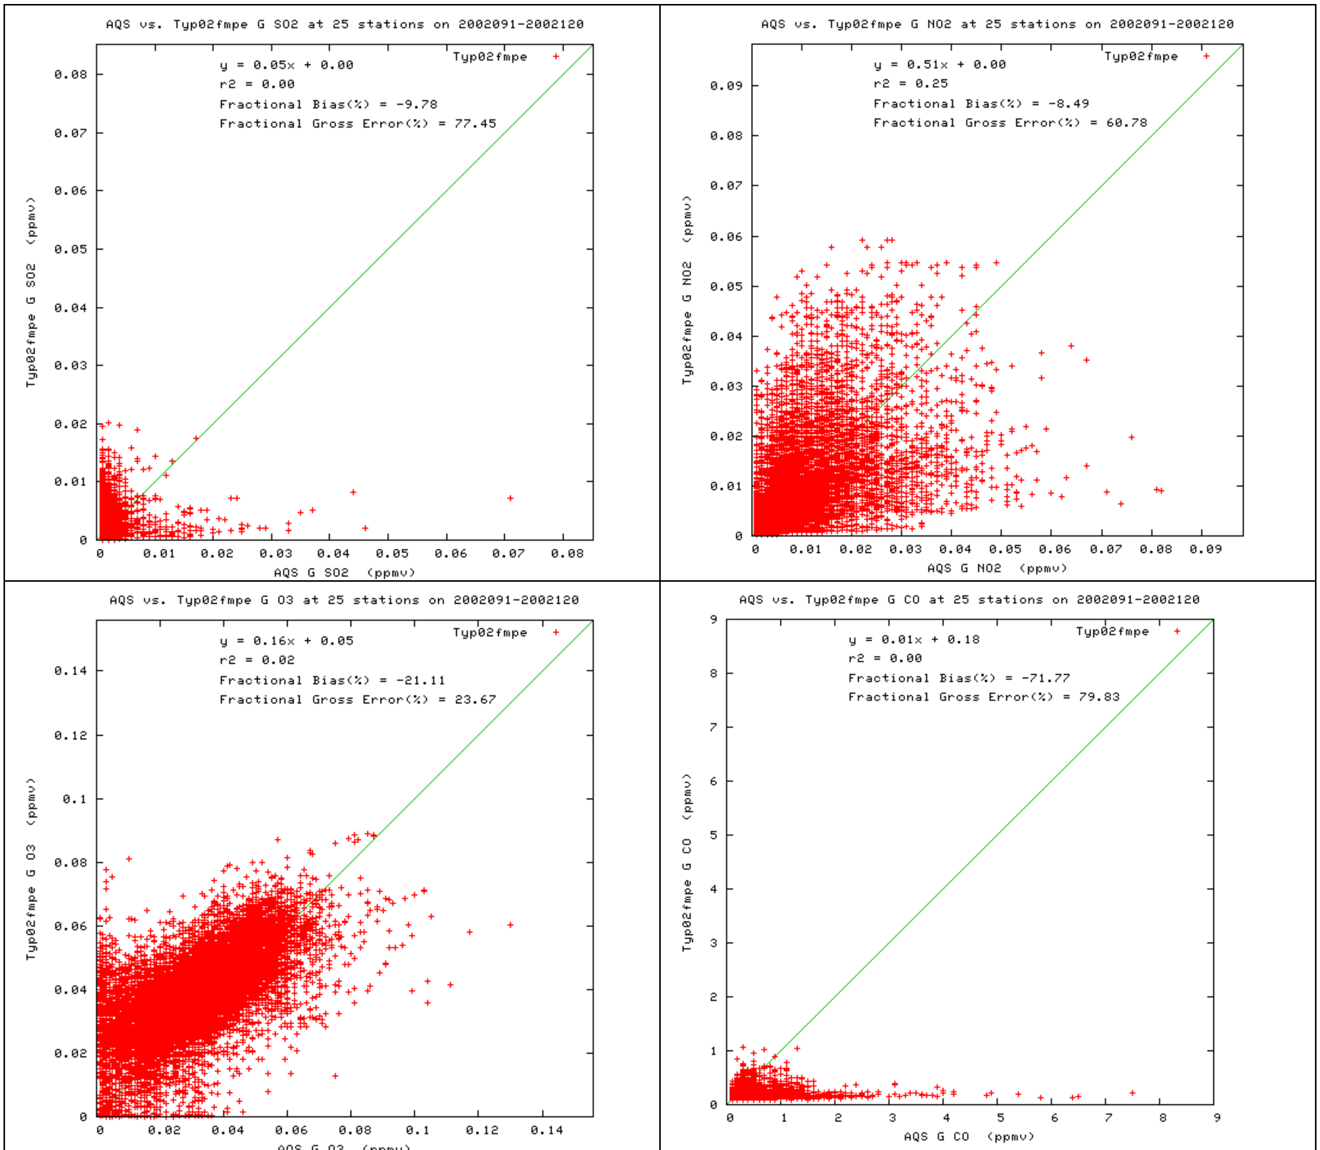

Figure C-43 April 2002 performance at CENRAP AQS sites for SO2 (top left), NO2 (top right), O3 (bottom left) and CO (bottom right).

C.4.3 Diagnostic Model Performance In July

In July SO2 is slightly underestimated across the CASTNet (-5%) and AQS (-12%) networks (Figures C-44 and C-45) and SO4 is more significantly underestimated across all networks (-22% to -53%, Figure C-6a). Since wet SO4 is also underestimated it is unclear the reasons for why all sulfur species are underestimated.

The nitrate species are also all underestimated with the Total NO3 bias (-56%) being between the HNO3 bias (-35%) and NO3 bias (-115%). The modeled NO3 values are all near zero with little correlation with the observations, whereas the observed HNO3 and Total NO3 is tracked well with correlation coefficients of 0.74 and 0.76. These results suggest that the July NO3 model performance problem is partly due to insufficient formation of Total NO3 and mainly due to too little incorrect partitioning of the Total NO3 into the particle NO3.

Again there is lots of scatter in the AQS NO2 scatter plot for July (Figure C-45) resulting in a low bias (0%) but high error (65%). Ozone performance also exhibits a low bias (-15%) and error (20%), but the model is incapable of simulating ozone above 100 ppb. Although CO performance in July is better than the previous months, it still has a large underestimation bias (-82%).

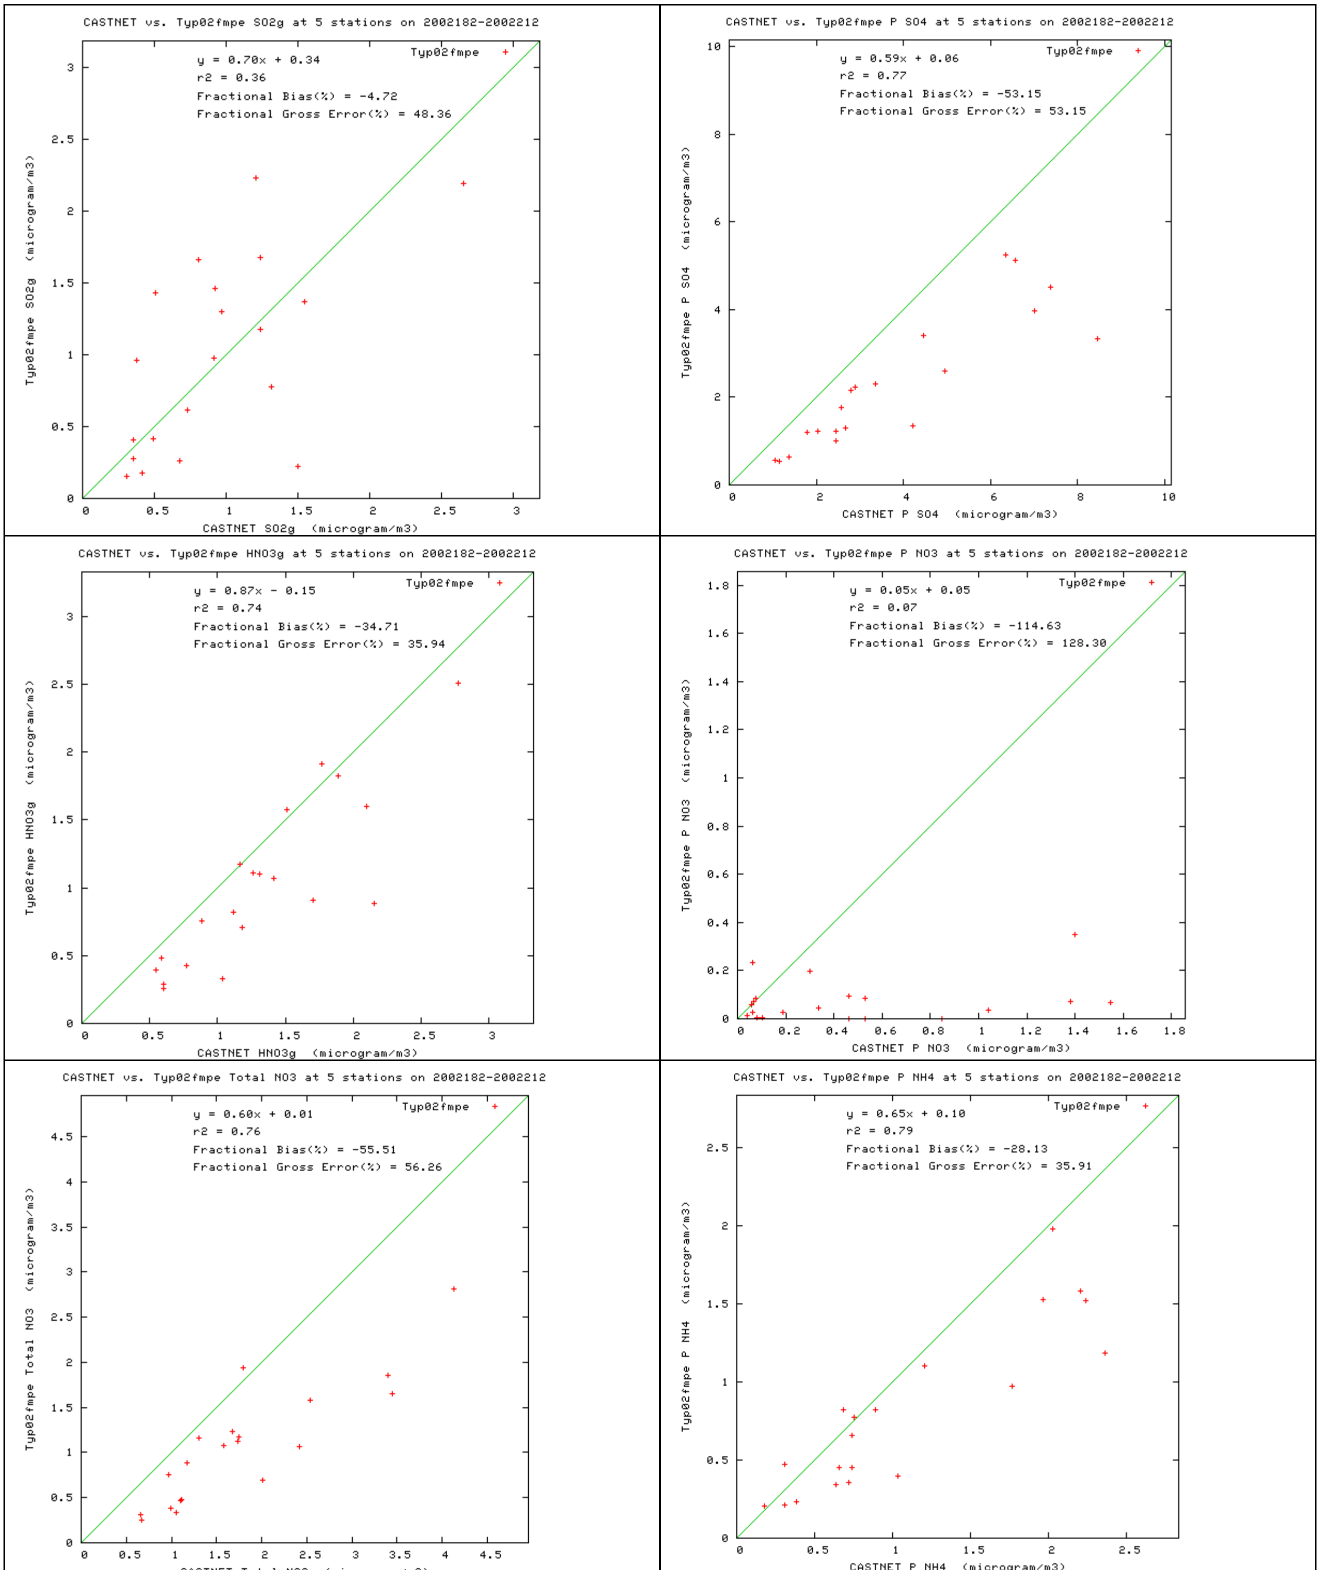

Figure C-44 July 2002 performance at CENRAP CASTNet sites for SO2 (top left), SO4 (top right), HNO3 (middle left), NO3 (middle right), Total NO3 (bottom left) and NH4 (bottom right).

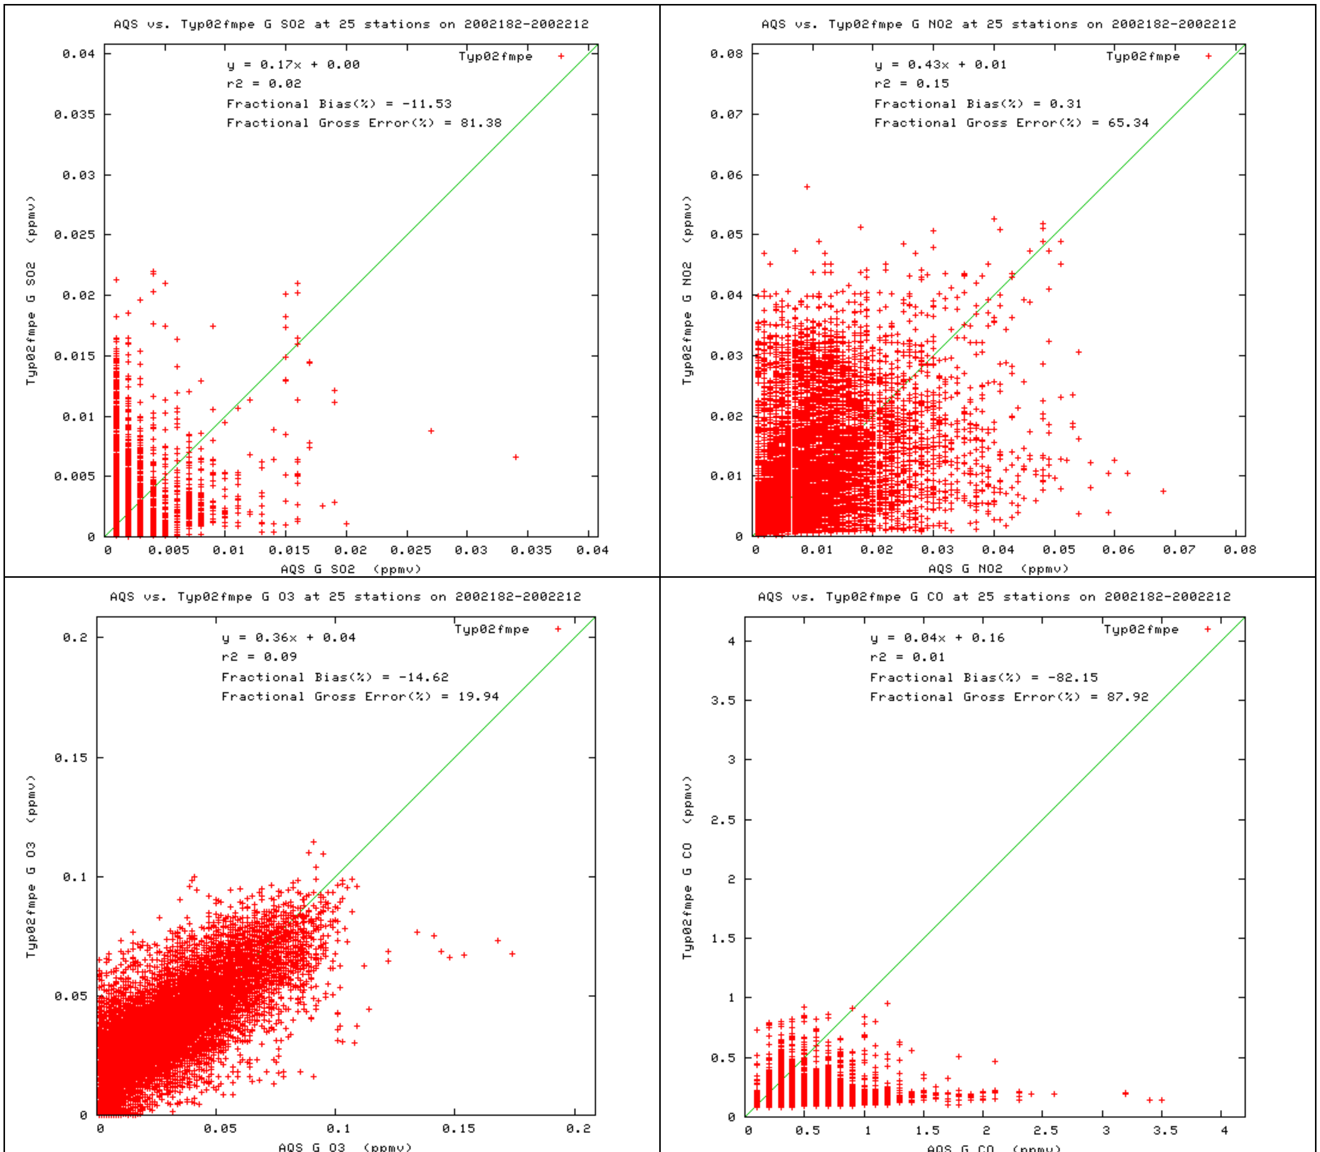

Figure C-45 July 2002 performance at CENRAP AQS sites for SO2 (top left), NO2 (top right), O3 (bottom left) and CO (bottom right).

C.4.4 Diagnostic Model Performance In October

SO2 is overstated in October across the CASTNet (+28%) and AQS (+33%) sites (Figures C-46 and C-47). Although SO4 is understated across the CASTNet sites (-24%), the bias across the IMPROVE (-6%) and STN (0%) sites are near zero (Figure C-7a).

Performance for HNO3 is fairly good with a low bias (+12%) and error (30%). But NO3 is overstated (+34%) leading to an overstatement of Total NO3 (+37%). The overstatement of NO3 leads to an overstatement of NH4 as well (Figure C-46)

As seen in the other months, NO2 exhibits a lot of scatter resulting in a low correlation (0.22) and high error (61%) but low bias (12%). The model tends to under-predict the high and over-predict the low O3 observations resulting in a -29% bias and low correlation coefficient. CO is also under-predicted (-76%) for the reasons discussed previously.

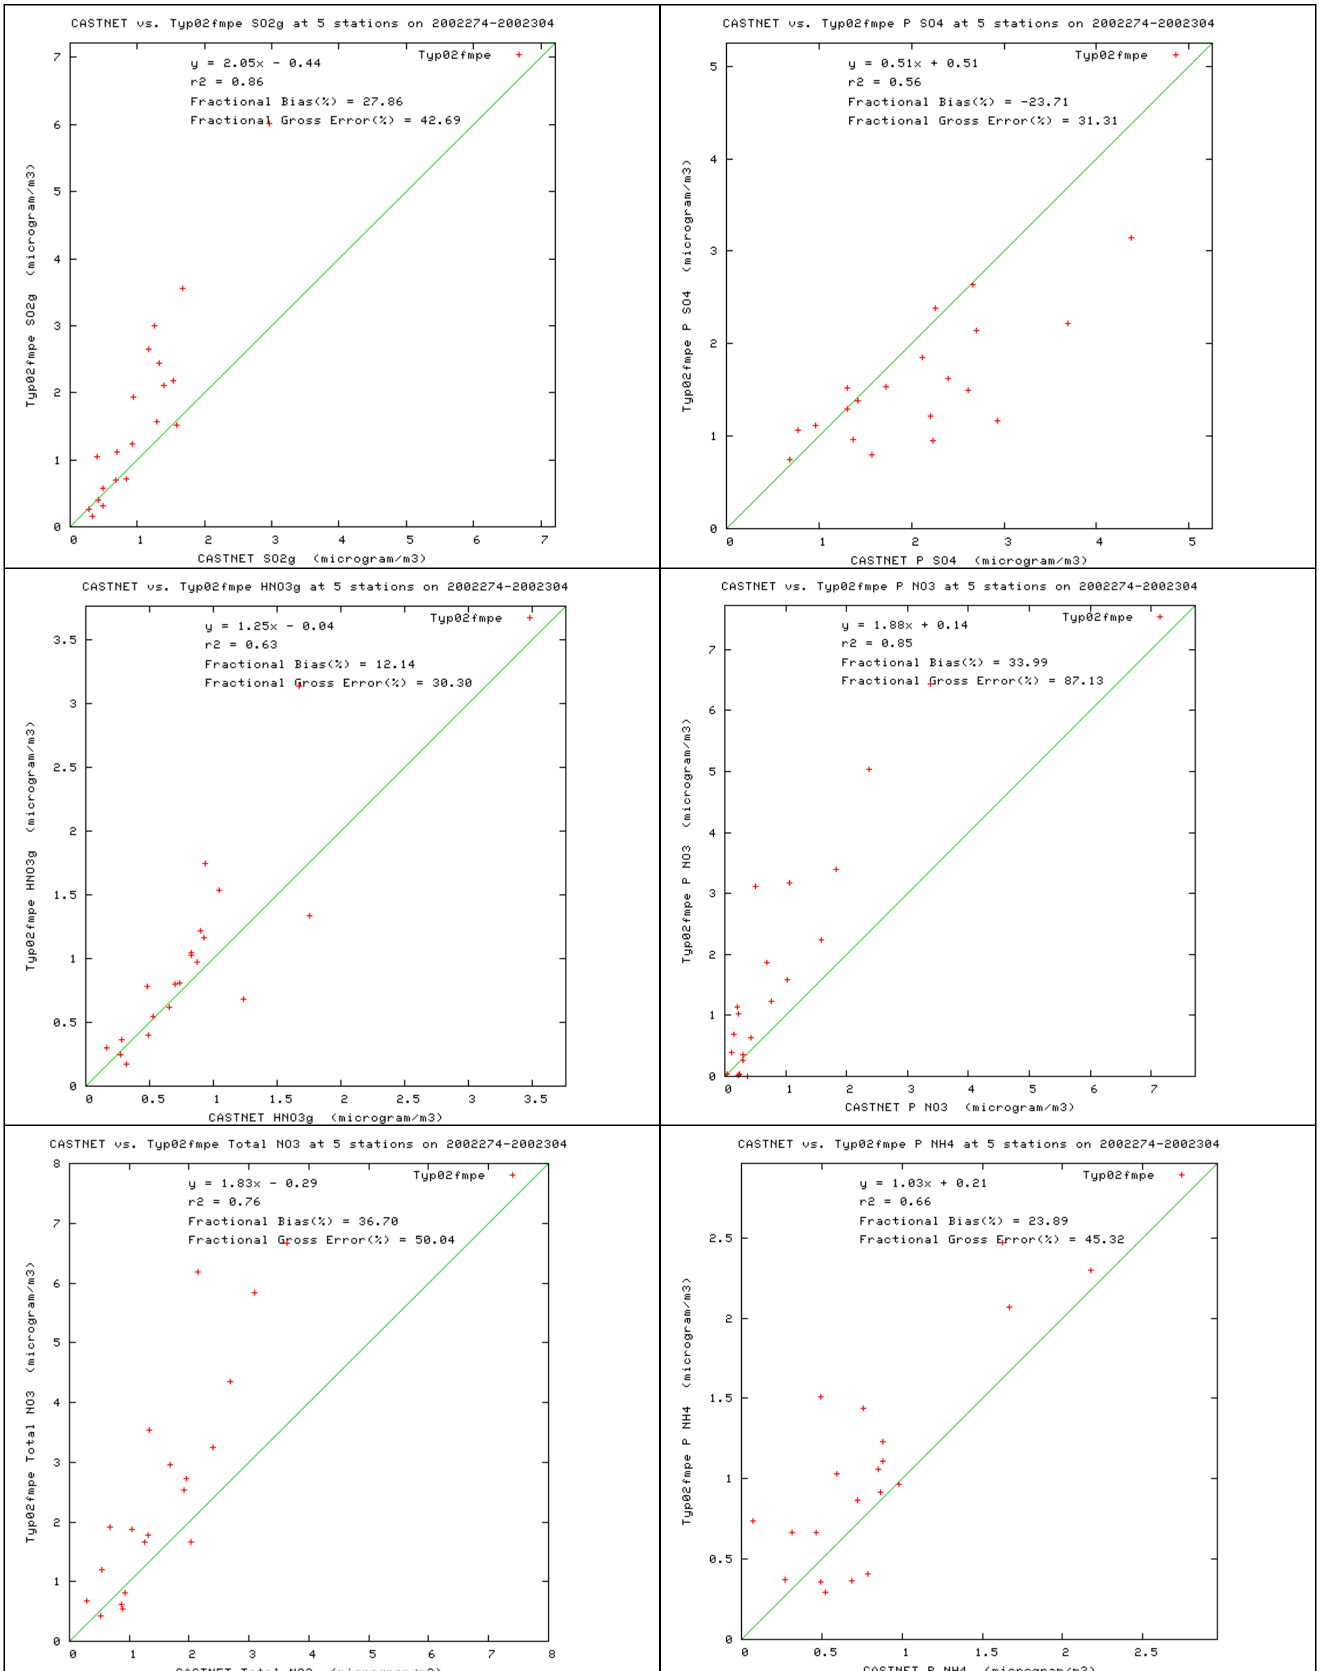

Figure C-46 October 2002 performance at CENRAP CASTNet sites for SO2 (top left), SO4 (top right), HNO3 (middle left), NO3 (middle right), Total NO3 (bottom left) and NH4 (bottom right).

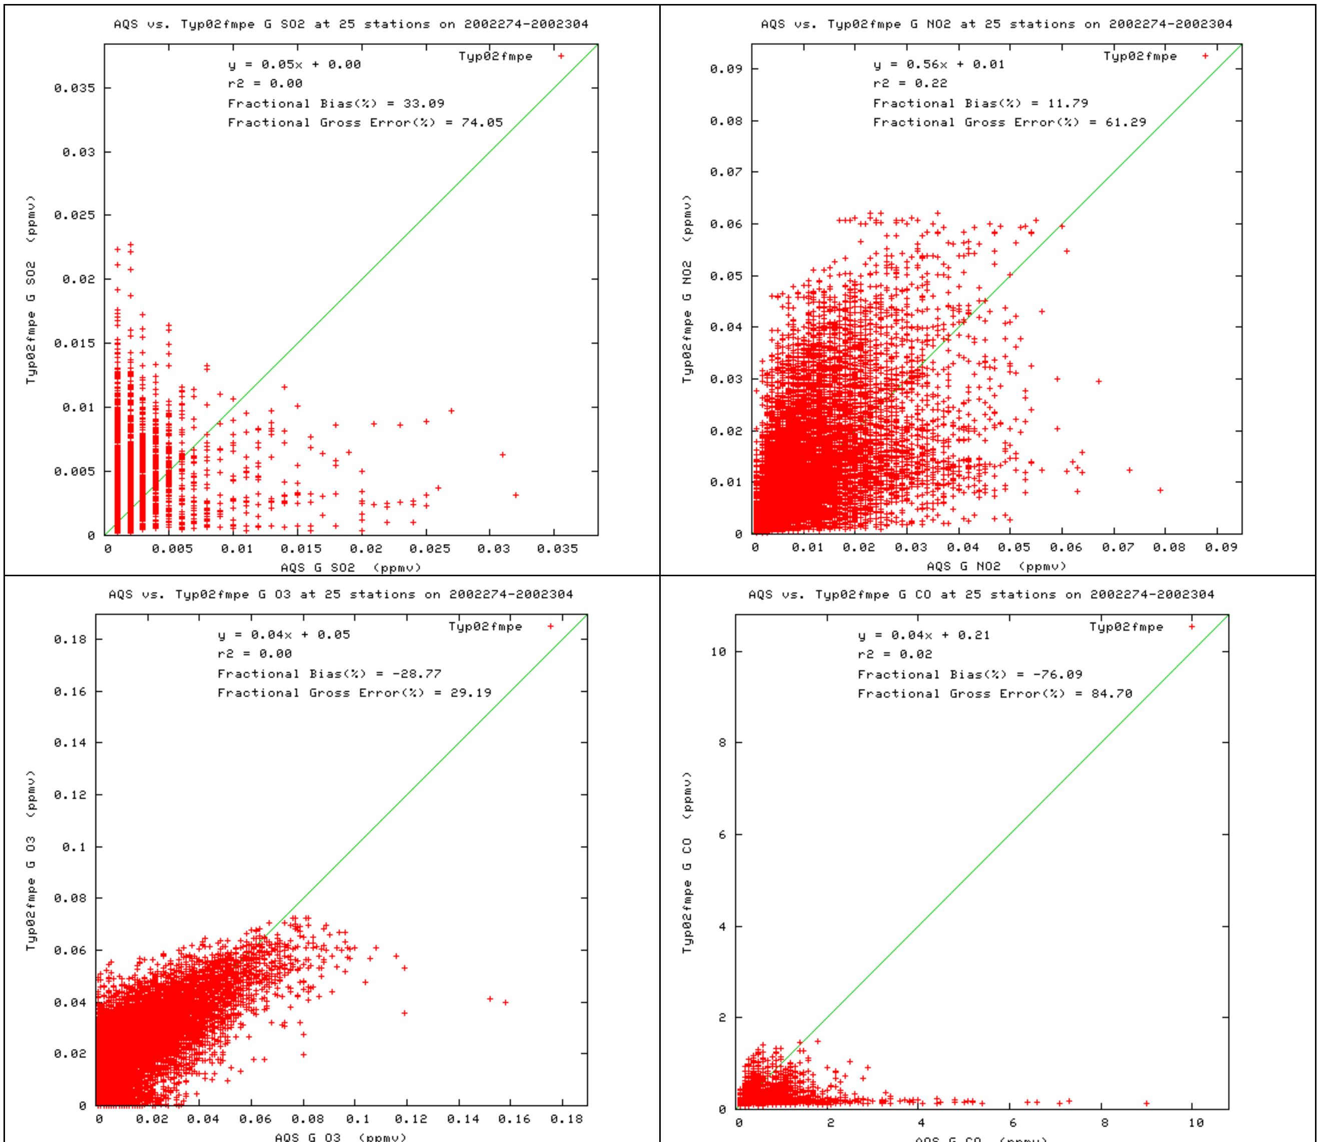

Figure C-47 October 2002 performance at CENRAP AQS sites for SO2 (top left), NO2 (top right), O3 (bottom left) and CO (bottom right).

C.5 Evaluation at Class I Areas for the Worst and Best 20 Percent Days

In this section, and in section C.5 of Appendix C, we present the results of the model performance evaluation at each of the CENRAP Class I areas for the worst and best 20 percent days. Performance on these days is critical since they are the days used in the 2018 visibility projections discussed in Chapter 4. For each Class I area we compared the predicted and observed total extinction (these figures are in Chapter 3) and PM species-specific extinction for the worst and best 20 percent days in 2002.

C.5.1 Caney Creek (CACR) Arkansas

The ability of the CMAQ model to estimate visibility extinction at the CACR Class I area on the 2002 worst and best 20 percent days is provide in Figures 3-9 and C-48. On most of the worst 20 percent days at CACR total extinction is dominated by SO4 extinction with some extinction due to OMC. On four of the worst 20 percent days extinction is dominated by NO3. The average extinction across the worst 20 percent days is underestimated by -33% (Figure 3-9), which is primarily due to a -51% underestimation of SO4 extinction combined with a 6% overestimation of NO3 extinction (Figure C-48). Performance for OMC extinction at CACR on the worst 20 percent days is pretty good with a -20% bias and 36% error, EC extinction is systematically underestimated, Soil extinction has low bias (-19%) buts lots of scatter and high error (74%), while CM extinction is greatly underestimated (bias of -153%).

On the best 20 percent days at CACR the observed extinction ranges from 20 to 40 Mm^{-1}, whereas then modeled extinction has a much larger range from 15 to 120 Mm^{-1}. Much of the modeled overestimation of total extinction on the best 20% days (+44% bias) is due to NO3 overestimation (+94% bias).

C.5.2 Upper Buffalo (UOBU) Arkansas

Model performance at the UPBU Class I area for the worst and best 20 percent days is shown in Figures 3-10 and C-49. On most of the worst 20 percent days at UPBU visibility impairment is dominated by SO4, although there are also two high NO3 days. The model underestimates the average of the total extinction on the worst 20 percent days at UPBU by -40% (Figure 3-10), which is due to an underestimation of extinction due to SO4, OMC and CM by, respectively,
-46%, -33% and -179%.

On the best 20 percent days at UPBU, the model performs reasonably well with a low bias (2%) and error (42%). But again the model has a much wider range in extinction values across the best 20 percent days (15 to 120 Mm^{-1}) than observed (20 to 45 Mm^{-1}). There are five days in which the modeled NO3 over-prediction is quite severe and when those days are removed the range in the modeled and observed extinction on the best 20 percent days is quite similar, although the model gets much cleaner on the very cleanest modeled days.

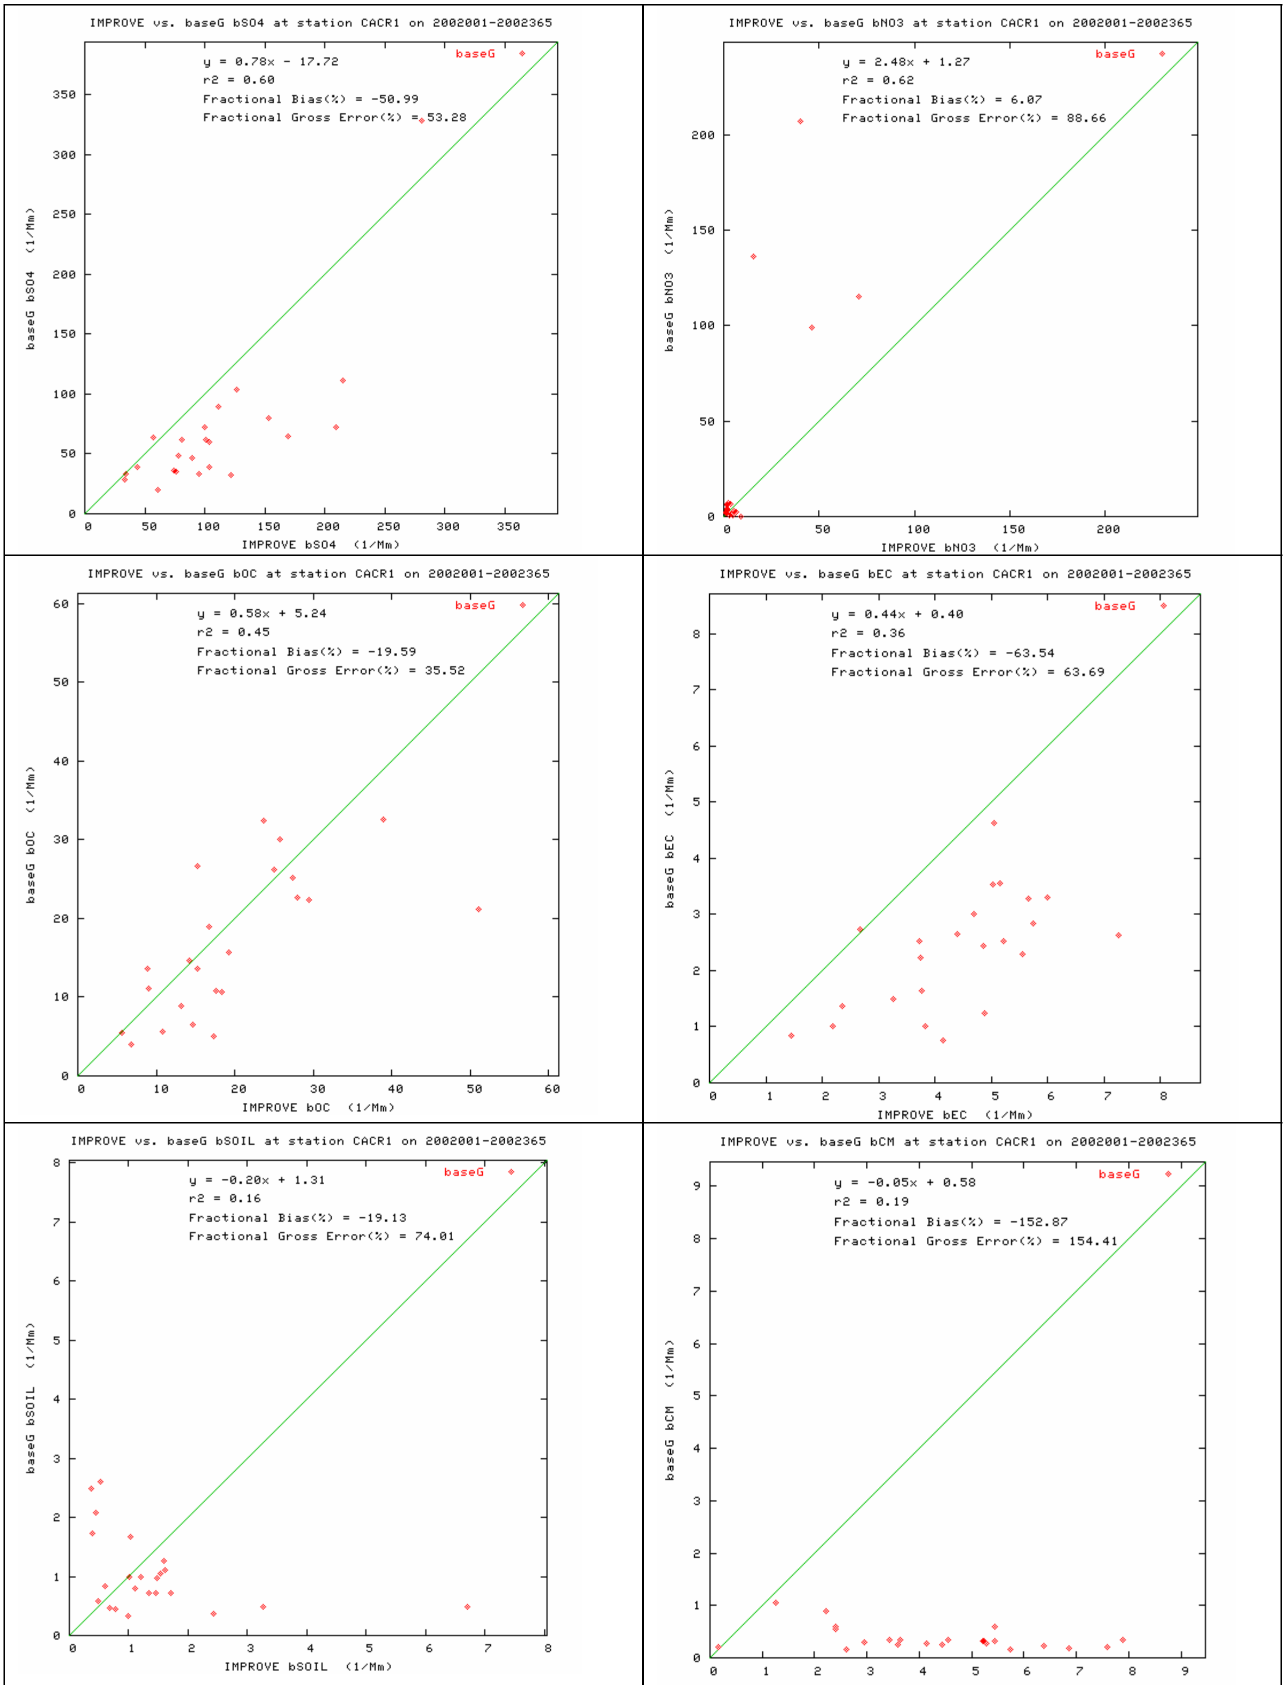

Figure C-48. PM species extinction model performance at Caney Creek (CACR) for the worst 20 percent days during 2002.

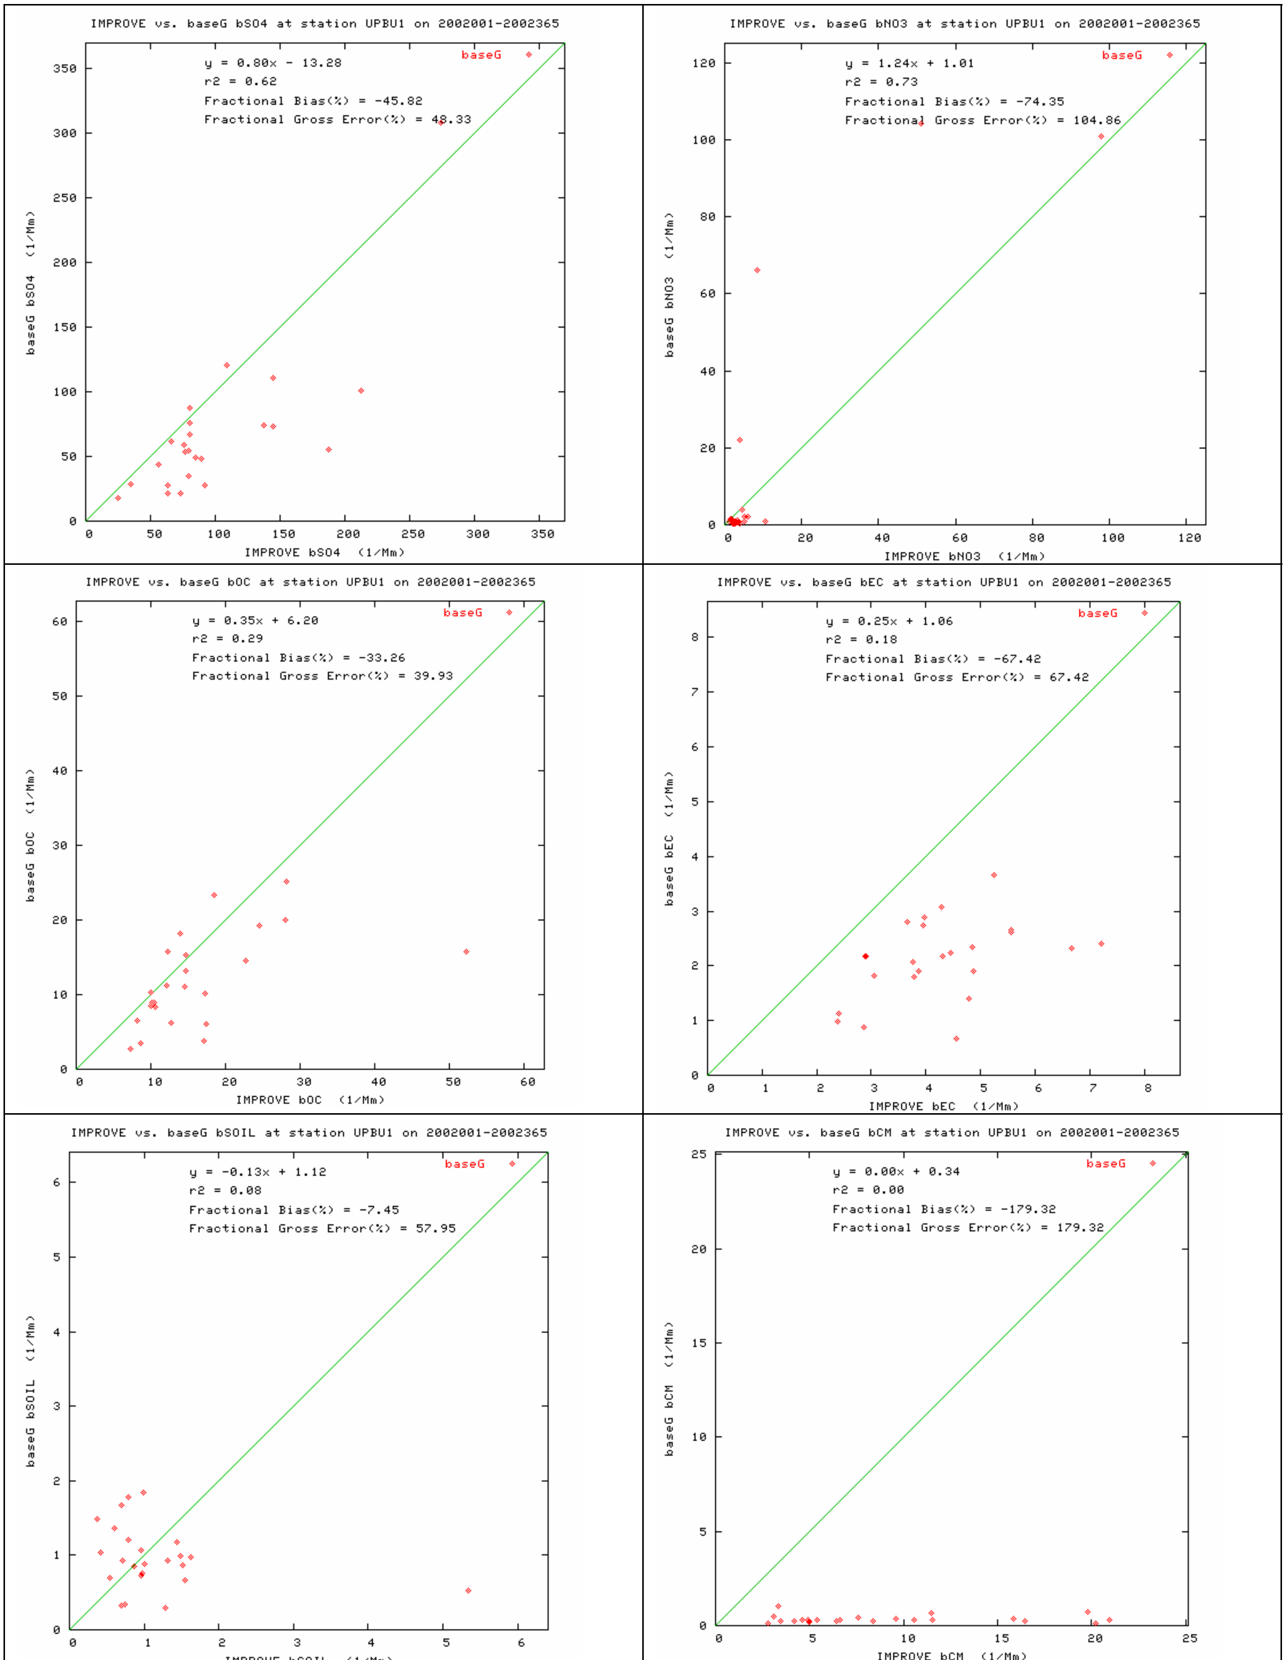

Figure C-49. PM species extinction model performance at Upper Buffalo (UPBU) for the worst 20 percent days during 2002.

C.5.3 Breton Island (BRET), Louisiana

The observed total extinction on the worst 20 percent days at Breton Island is underestimated by -71% (Figure 3-11), which is due to an underestimation of each component of extinction (Figure C-50) by from -50% to -70% (SO4, OMC and Soil) to over -100% (EC and CM). The observed extinction on the worst 20 percent days ranges from 90 to 170 Mm^{-1}, whereas the modeled values drop down to as low as approximately 15 Mm^{-1}. On the best 20 percent days the range of the observed and modeled extinction is similarly (roughly 10 to 50 Mm^{-1}) that results in a reasonably low bias (-22%), but there is little agreement on which days are higher or lower resulting in a lot of scatter and high error (54%).

C.5.4 Boundary Waters (BOWA), Minnesota

There are three types of days during the worst 20 percent days at BOWA, SO4 days, OMC days and NO3 days (Figure 3-12). The two high OMC days are likely fire impact events that the model captures to some extent on one day and not on the other. On the five high (> 20 Mm^{-1}) NO3 extinction days the model predicts the observed extinction well on three days and overestimates by a factor of 3-4 on the other two high NO3 days. SO4 in underestimate by -43% on average across the worst 20 percent days at BOWA.

With the exception of two days, the model reproduces the total extinction for the best 20 percent days at BOWA quite well with a bias and error value of +14% and 22% (Figure 3-12). Without these two days, the modeled and observed extinction both range between 15 and 25 Mm^{-1}.

C.5.5 Voyageurs (VOYA) Minnesota

VOYA is also characterized by SO4, NO3 and OMC days (Figure 3-13). Julian Days 179 and 200 are high OMC days that were also high OMC days at BOWA again indicating impacts from fires in the area that is not fully captured by the model. SO4 and NO3 extinction is fairly good and, without the fire days, OMC performance looks good as well (Figure C-52). On the best 20 percent days there is one day the modeled extinction is much higher than observed and a few others that are somewhat higher, but for most of the best 20 percent days the modeled extinction is comparable to the observed values.

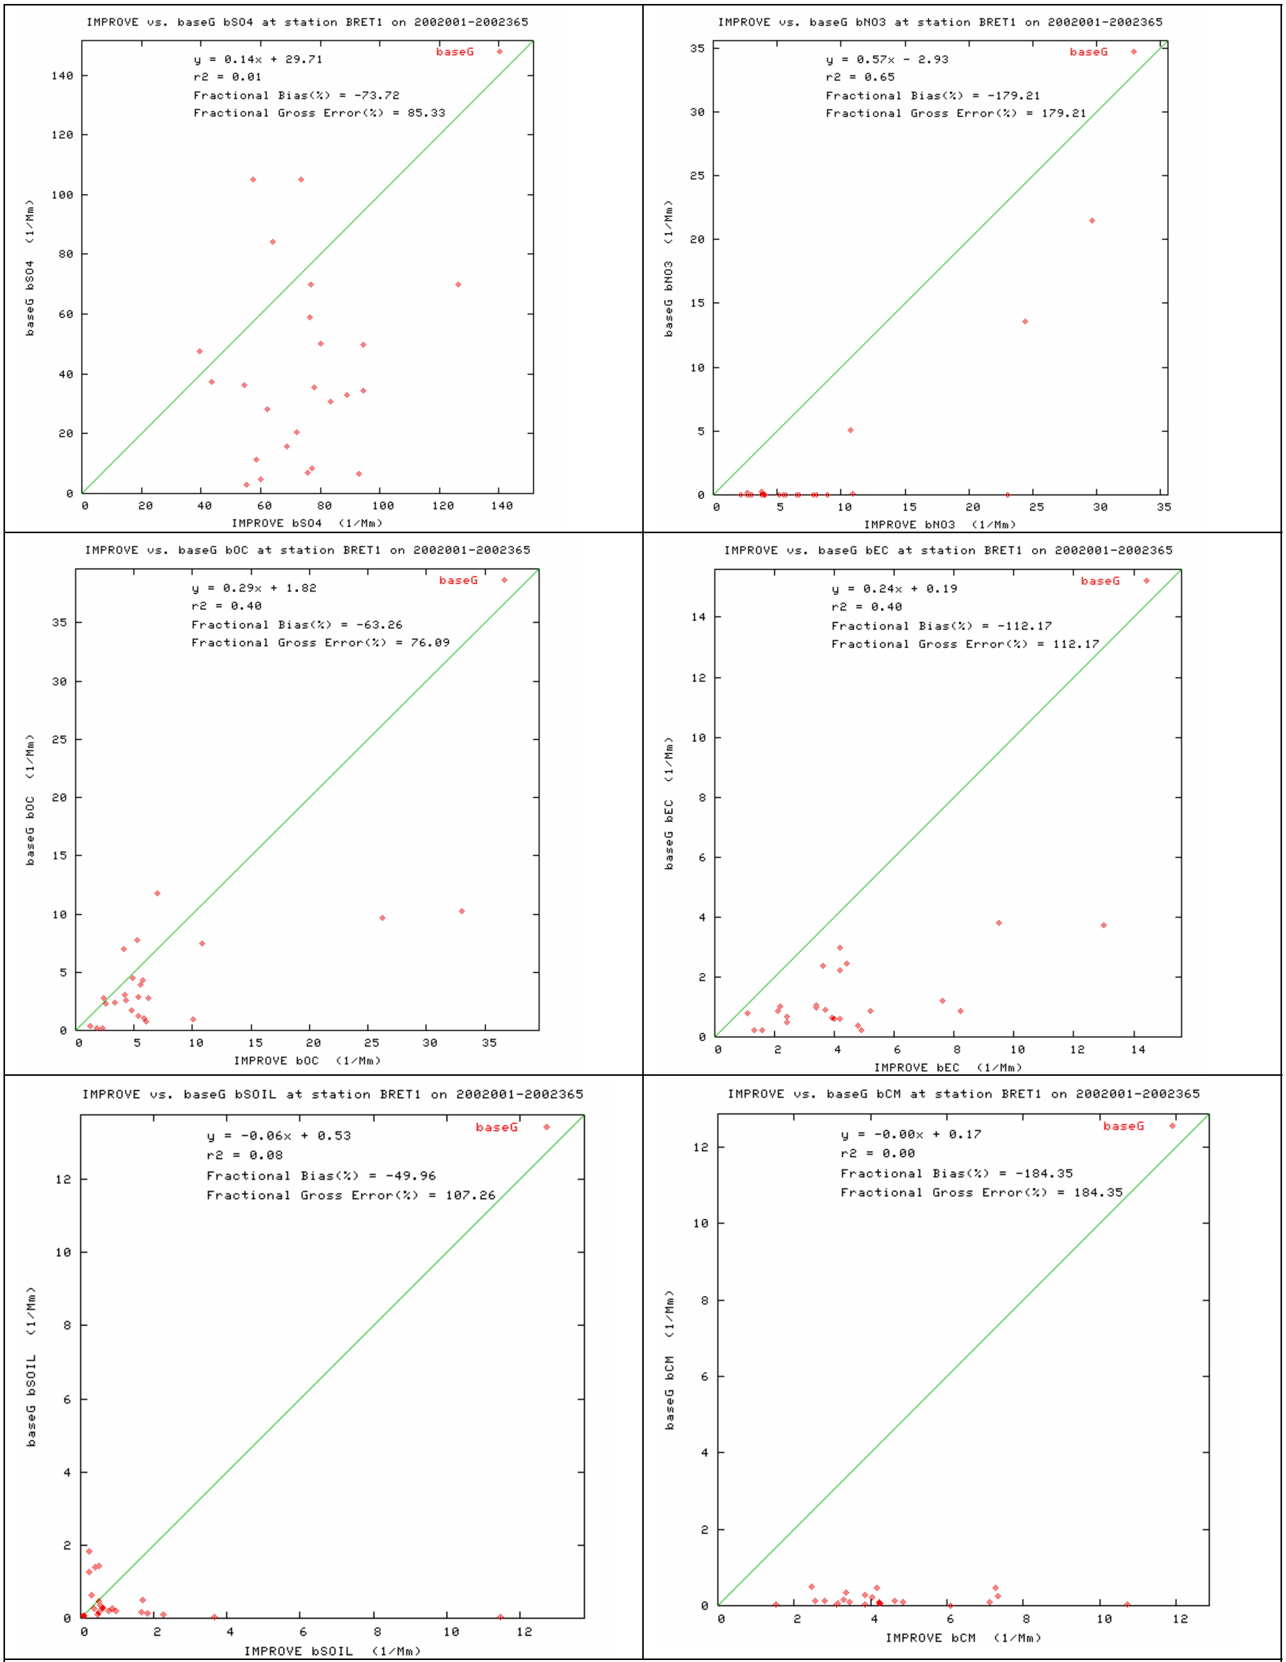

Figure C-50. PM species extinction model performance at Breton Island (BRET) for the worst 20 percent days during 2002.

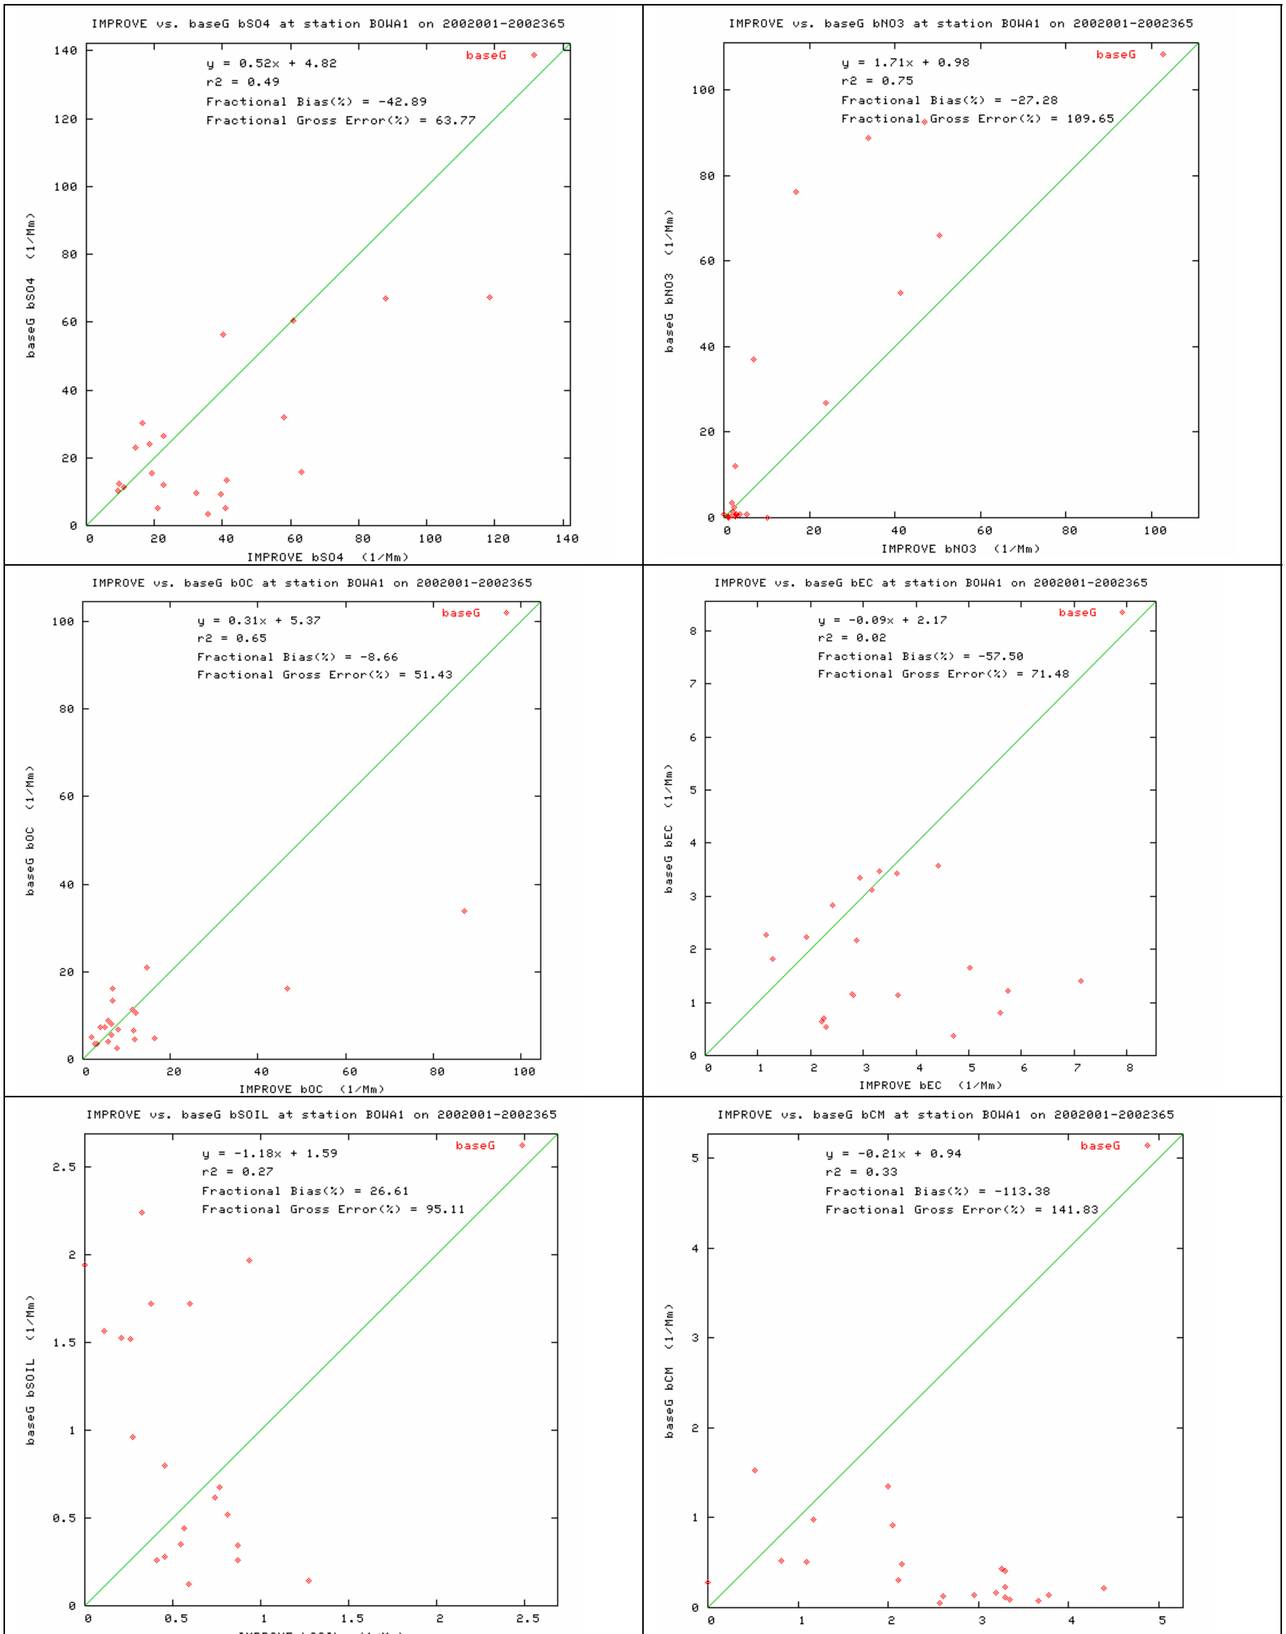

Figure C-51. PM species extinction model performance at Boundary Waters (BOWA) for the worst 20 percent days during 2002.

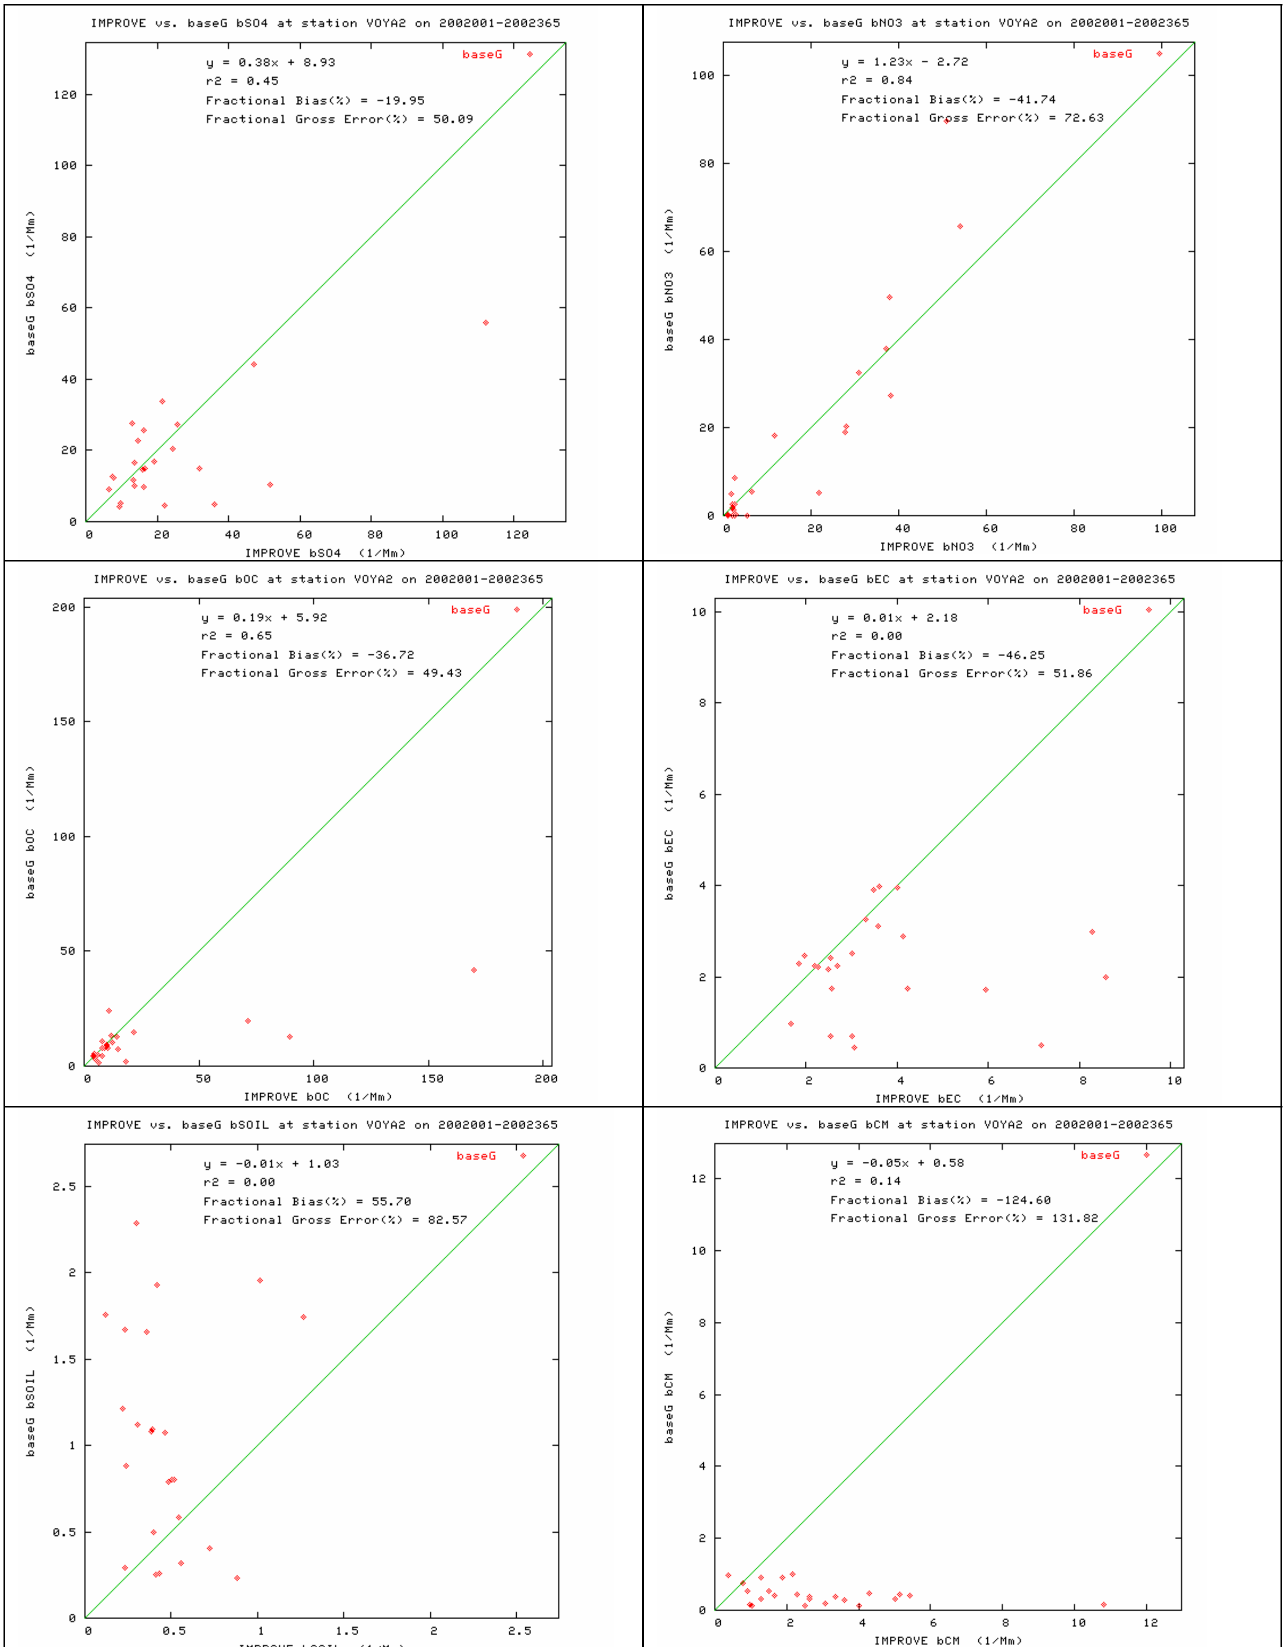

Figure C-52. PM species extinction model performance at Voyageurs (VOYA) for the worst 20 percent days during 2002.

C.5.6 Hercules Glade (HEGL) Missouri

On most of the worst 20 percent days at HEGL the observed extinction ranges from 120 to 220 Mm^{-1} whereas model extinction ranging from 50 to 170 Mm^{-1} (Figure 3-14). However, there is one extreme day with extinction approaching 400 Mm^{-1} that the model does a very good job in replicating. Over all the days there is a modest underestimation bias in SO4 (-39%) and OMC (-39%) extinction, larger underestimation bias in EC (-62%) and CM (-118%) extinction and overestimation bias in Soil (+30%) extinction (Figure C-53).

On the best 20 percent days there is one day where the model overstates the observed extinction by approximately a factor of four and a handful of other days that the model overstates the extinction by a factor of 2 or so, but most of the days both the model and observed extinction sites are around 40 Mm^{-1} plus or minus about 10 Mm^{-1}. On the best 20 percent days when the observed extinction is overstated it is due to overstatement of the NO3.

C.5.7 Mingo (MING) Missouri

The worst 20 percent days at Ming are mainly high SO4 days with a few high NO3 days that the model reproduces reasonably well resulting in low bias (+10%) and error (38%) for total extinction (Figure 3-15). The PM species specific performance is fairly good with low bias for SO4 (+4%), good agreement with NO3 on high NO3 days except for one day, low OMC (+23%) and EC (+3%) bias and larger bias in EC (+37%) and CM (-105%) extinction (Figure C-54).

For the best 20 percent days, there is one day the model is way to high due to overstated NO3 extinction and a few other days the model overstates the observed extinction that is usually due to overrated NO3, but on most of the best 20 percent days the modeled extinction is comparable to the observed values. This results in low bias (+12%) and error (36%) for total extinction at MING for the best 20 percent days.

C.5.8 Wichita Mountains (WIMO), Oklahoma

With the exception of an over-prediction on day 344 due to NO3, observed total extinction on the worst 20 percent days at WIMO is understated with a bias of -42% (Figure 3-16) that is primarily due to an underestimation of extinction due to SO4 (-48%) and OMC (-69%) (Figure C-55).

CMAQ total extinction performance for the average of the best 20 percent days at WIMO is characterized by an overestimation bias (+21%) on most days that is primarily due to NO3 over-prediction on several days. Again the modeled range of extinction on the best 20 percent days (12-60 Mm^{-1}) is much greater than observed (20-35 Mm^{-1}).

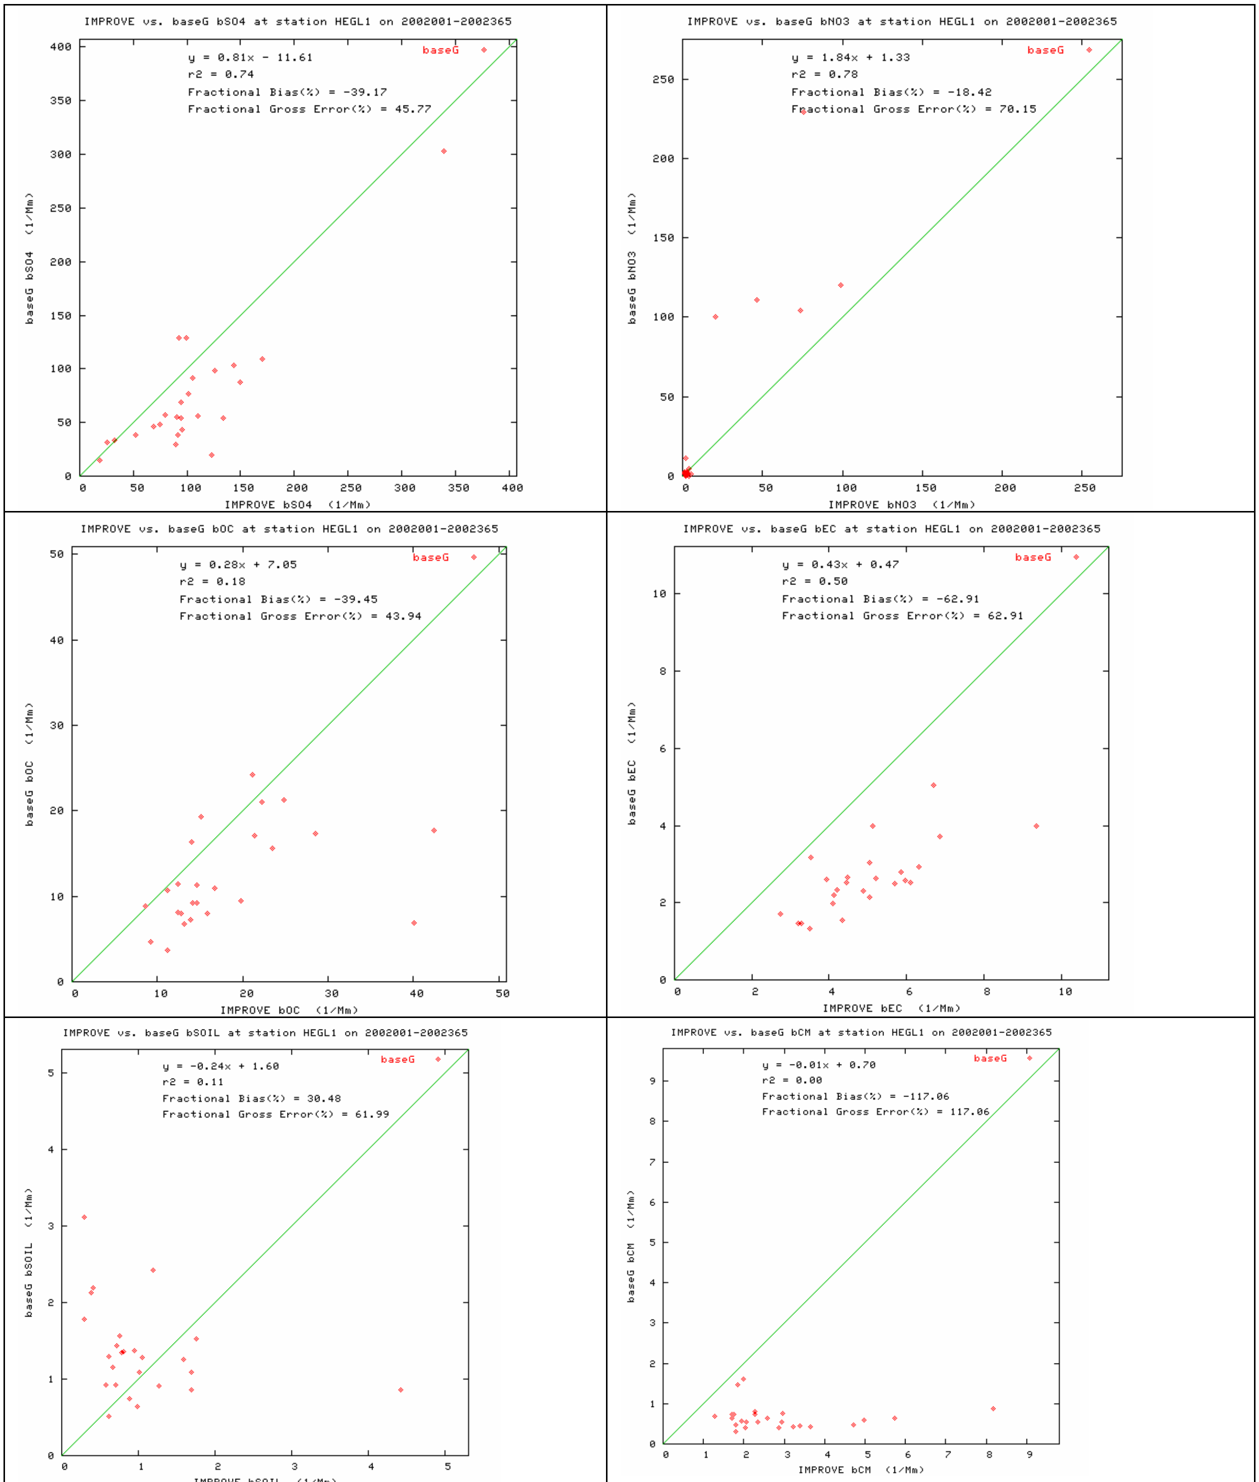

Figure C-53. PM species extinction model performance at Hercules Glade (HEGL) for the worst 20 percent days during 2002.

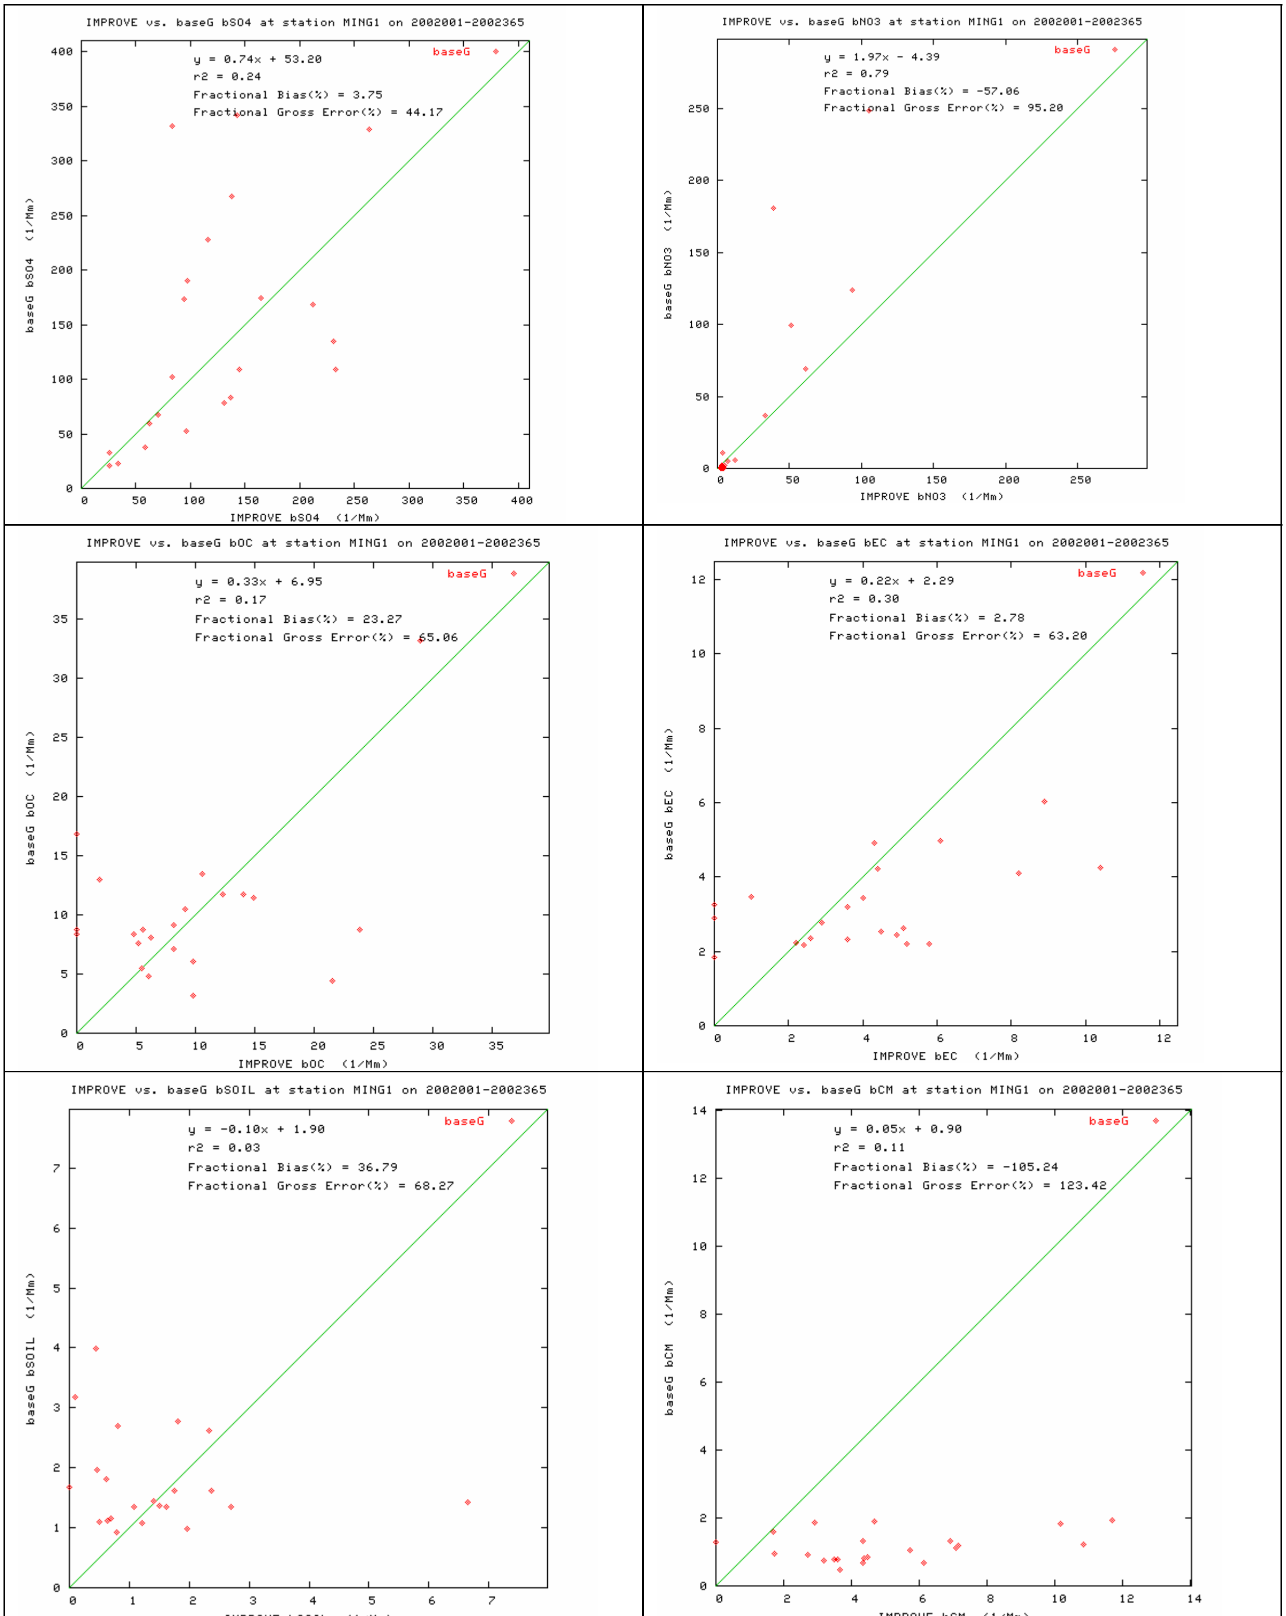

Figure C-54. PM species extinction model performance at Mingo (MING) for the worst 20 percent days during 2002.

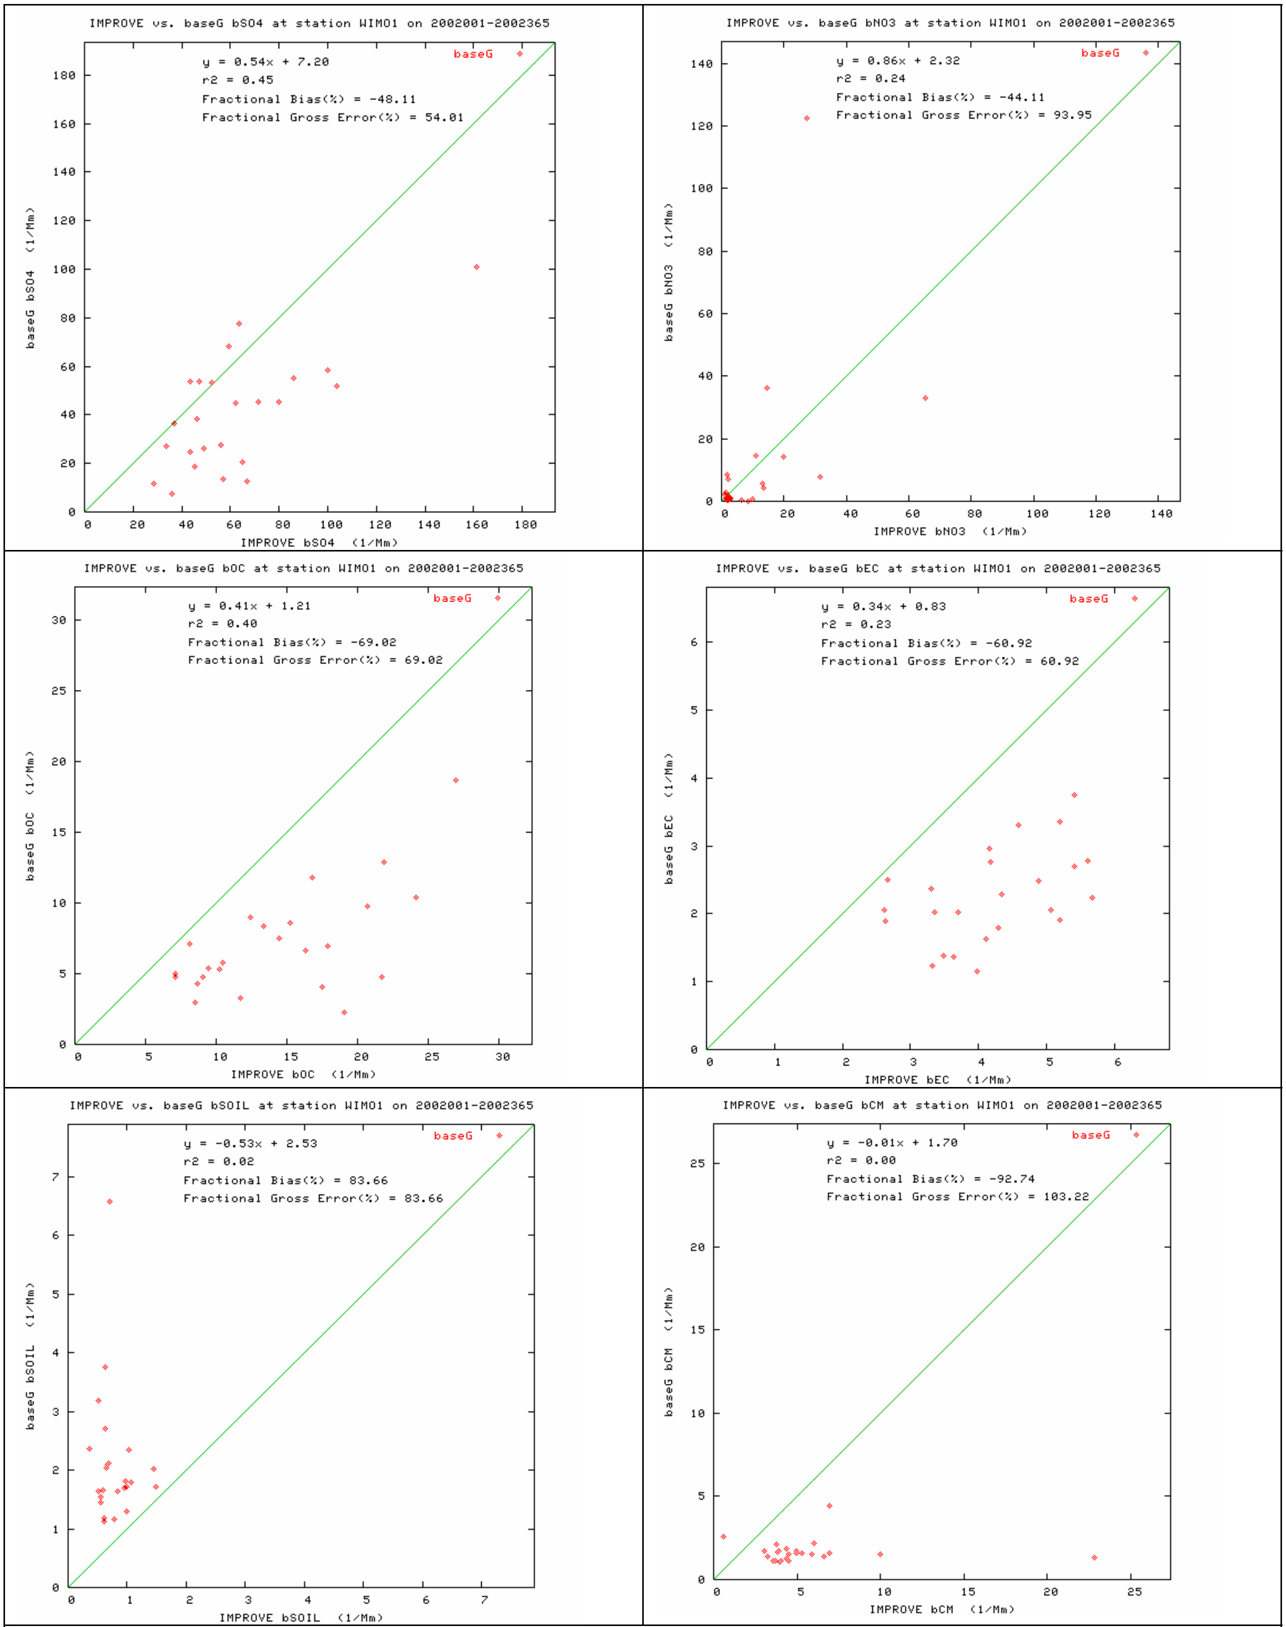

Figure C-55. PM species extinction model performance at Wichita Mountains (WIMO) for the worst 20 percent days during 2002.

C.5.9 Big Bend (BIBE) Texas

The observed extinction on the worst 20 percent days at BIBE is under-predicted on almost every day resulting in a fractional bias value of -72% (Figure 3-17). Every component of extinction is underestimated on average for the worst 20 percent days (Figure C-56) with the underestimation bias ranging from -24% (OMC) to -162% (CM). SO4 extinction, that typically represents the largest component of the total extinction is understated by -94%.

The model does a better job in predicting the total extinction at BIBE for the best 20 percent days with average fractional bias and error values of +13% and 19% (Figure 3-17). With the exception of one day that the observed extinction is overestimated by approximately a factor of 2, the modeled and observed extinction on the best 20 percent days at BIBE are both within 12 to 25 Mm^{-1}. However, there are some mismatches with the components of extinction with the model estimating much lower contributions due to Soil and CM.

C.5.10 Guadalupe Mountains (GUMO) Texas

Most of the worst 30 percent days at GUMO are dust days with high Soil and CM that is not at all captured by the model (Figure 3-18). Extinction due to Soil and CM on the worst 20 percent days is underestimated by -105% and -191%, respectively (Figure C-57). Better performance is seen on the best 20 percent days with bias and error for total extinction of 8% and 21%, but the model still understates Soil and CM.

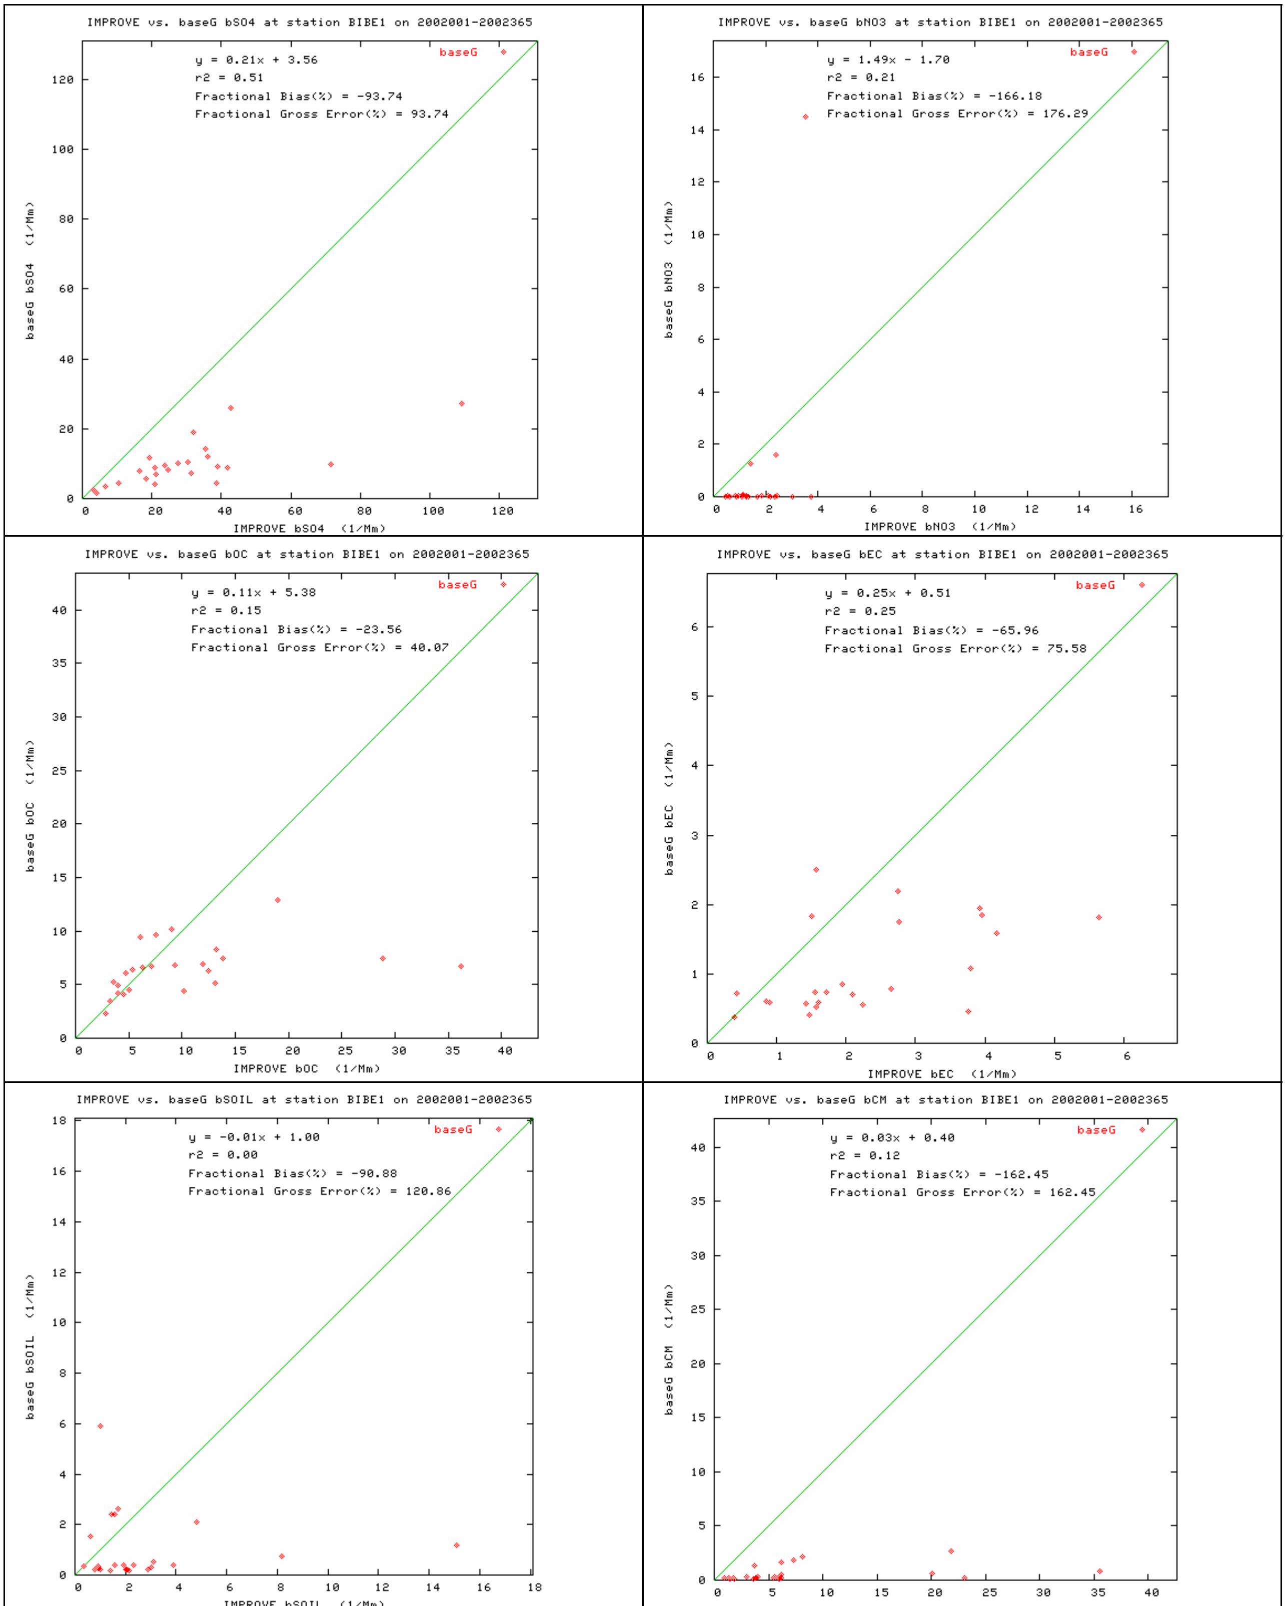

Figure C-56. PM species extinction model performance at Big Bend (BIBE) for the worst 20 percent days during 2002.

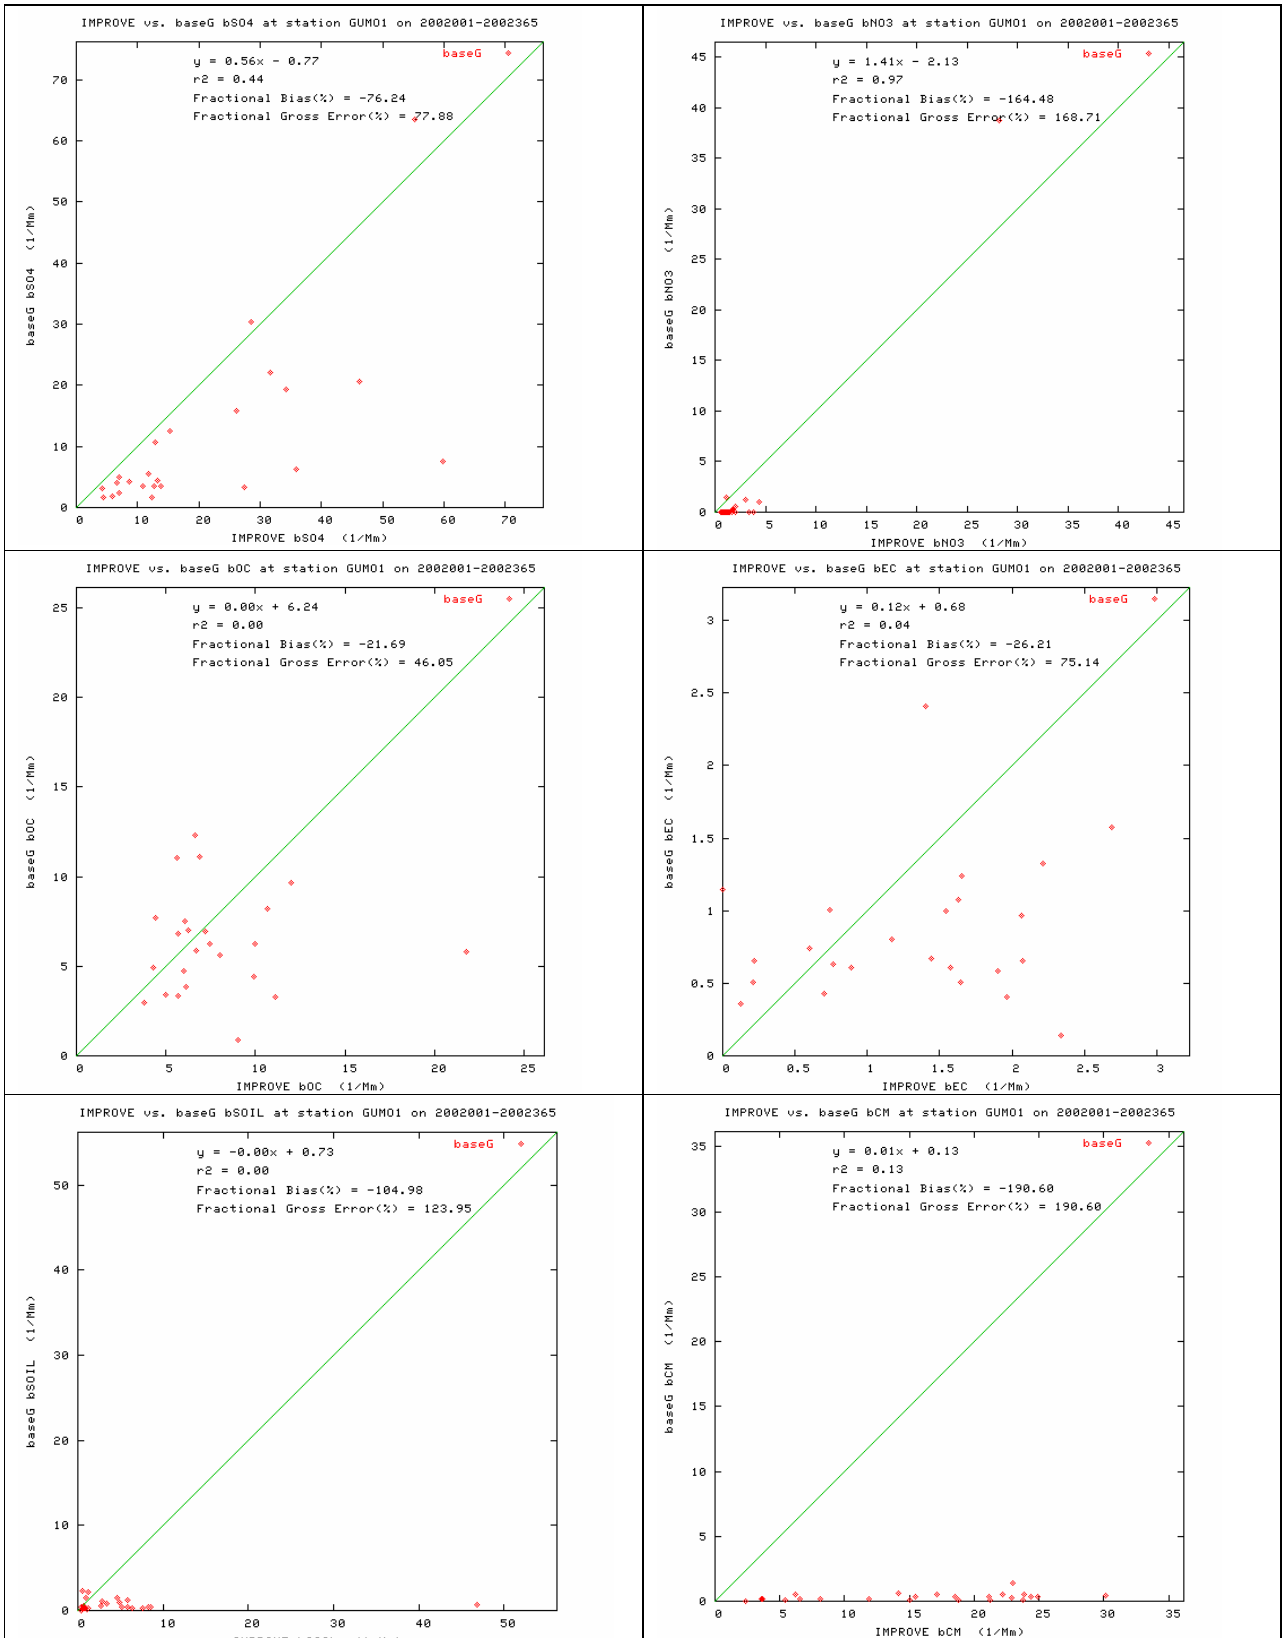

Figure C-57. PM species extinction model performance at Guadalupe Mountains (GUMO) for the worst 20 percent days during 2002.

C.6 Model Performance Evaluation Conclusions

The model performance evaluation reveals that the model is performing best for SO4, OMC and EC. Soil performance is mixed with winter overestimation bias but lower bias but high error in the summer. CM performance is poor year round. The operational evaluation reveals that SO4 performance usually achieves the PM model performance goal and always achieves the model performance criteria, although it does have an underestimation bias that is greatest in the summer. NO3 performance is characterized by a winter overestimation bias with an even greater summer underestimation bias. However, the summer underestimation bias occurs when NO3 is very low and it is not an important component of the observed or predicted PM and visibility impairment. Performance for OMC meets the model performance goal year round at the IMPROVE sites, but is characterized by an underestimation bias at the more urban STN sites. EC exhibits very low bias at the STN sites and a summer underestimation bias at the IMPROVE sites, but meets the model performance goal throughout the year. Soil has a winter overestimation bias that exceeds the model performance goal and criteria raising questions whether the model should be used for this species. Finally, CM performance is extremely poor with an under-prediction bias that exceeds the performance goal and criteria. We suspect that much of the CM concentrations measured at the IMPROVE sites is due to highly localized emissions that can not be simulated with 36 km regional modeling.

Performance for the worst 20 percent days at the CENRAP Class I areas is generally characterized by an underestimation bias. Performance at the BRET, BIBE and GUMO Class I areas for the worst 20 percent days is particularly suspect and care should be taken in the interpretation of the visibility projections at these three Class I areas.

The CMAQ 2002 36 km model appears to be working well enough to reliably make future-year projections for changes in SO4, NO3, EC and OMC at the rural Class I areas. Performance for Soil and especially CM is suspect enough that care should be taken in interpreting these modeling results. The model evaluation focused on the model's ability to predict the components of light extinction mainly at the Class I areas. Additional analysis would have to be undertaken to examine the model's ability to treat ozone and fine particulate to address 8-hour ozone and $PM_{2.5}$ attainment issues.

APPENDIX D

Revised IMPROVE Algorithm for Estimating Light Extinction from Particle Speciation Data

Revised IMPROVE Algorithm for Estimating Light Extinction from Particle Speciation Data

Section II. Overview of the Revised Algorithm

(IMPROVE technical subcommittee for algorithm review)

The recommended revised algorithm is shown in the equation below with revised terms in bold font. The total sulfate, nitrate and organic carbon compound concentrations are each split into two fractions, representing small and large size distributions of those components. Though not explicitly shown in the equation, the organic mass concentration used in this new algorithm is 1.8 times the organic carbon mass concentration, changed from 1.4 times carbon mass concentration as used for input for the current IMPROVE algorithm. New terms have been added for sea salt (important for coastal locations) and for absorption by NO_2 (only used where NO_2 data are available). Site-specific Rayleigh scattering is calculated for the elevation and annual average temperature of each of the IMPROVE monitoring sites as shown in the Table A at the end of the document.

$$\begin{aligned} b_{ext} \approx\ & \quad \times \quad \times [\quad] + \quad \times \quad \times [\quad] \\ & + \quad \times \quad \times [\quad] + \quad \times \quad \times [\quad] \\ & + \quad \times [\quad] + \quad \times [\quad] \\ & + 10 \times [Elemental\ \ Carbon] \\ & + 1 \times [Fine\ \ Soil] \\ & + \quad \times \quad \times [\quad] \\ & + 0.6 \times [Coarse\ \ Mass] \\ & + \\ & + \quad \times [\quad] \end{aligned}$$

The apportionment of the total concentration of sulfate compounds into the concentrations of the small and large size fractions is accomplished using the following equations.

$$[Large\ \ Sulfate] = \frac{[Total\ \ Sulfate]}{20 \mu g / m^3} \times [Total\ \ Sulfate], \ \ for\ [Total\ \ Sulfate] < 20 \mu g / m^3$$

$$[Large\ \ Sultate] = [Total\ \ Sulfate]\ \ for\ [Total\ \ Sulfate] \geq 20\ \mu g\ /\ m^3$$

$$[Small\ Sulfate] = [Total\ Sulfate] - [Large\ \ Sulfate]$$

The same equations are used to apportion total nitrate and total organic mass concentrations into the small and large size fractions.

Sea salt is calculated as 1.8 x [***Chloride***], or 1.8 x [***Chlorine***] if the chloride measurement is below detection limits, missing or invalid. The algorithm uses three water growth adjustment term as shown in the Figure 2 and Table 1. They are for use with the small size distribution and the large size distribution sulfate and nitrate compounds and for sea salt (***f_S(RH), f_L(RH)*** and ***f_{SS}(RH)*** respectively).

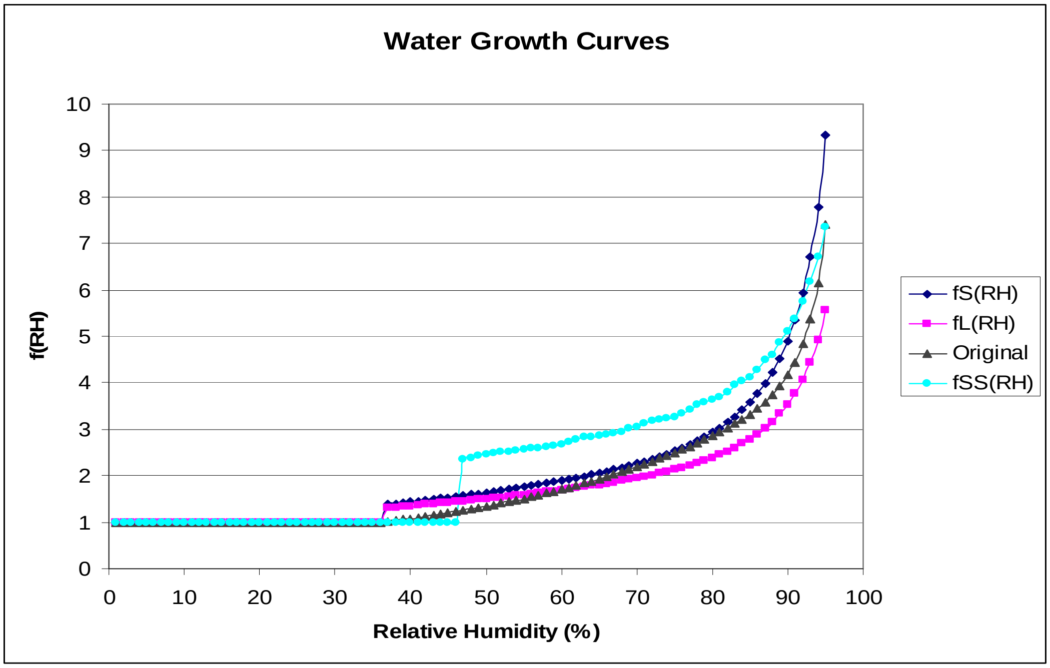

Figure 1. Water growth curves for small and large size distribution sulfate and nitrate, sea salt and the original IMPROVE algorithm sulfate and nitrate.

Algorithm Performance Evaluation

Performance of the current and proposed new algorithm for estimating extinction can be assessed in a number of ways each of which serves to answer different questions. Reduction of the biases in light scattering estimates at the extremes (i.e. underestimation of the high values and over estimation of the low values) when compared to nephelometer measurements was one of the most compelling reasons for development of a new algorithm, so comparisons of bias for the current and proposed new algorithm are one way to evaluate performance.

The fractional bias for each sample period was calculated as the difference in light scattering (i.e. estimated b_{sp} minus the measured b_{sp}) divided by the measured light scattering. These biases were then averaged in each quintile to indicate the bias in those five subsets of the data from the lowest to the highest light scattering values. Two different approaches to this grouping by quintiles were performed, referred to as criteria 1 and 2.

Criterion 1 used the measured light scattering to determine which sample periods were in each quintile. Since we think of the nephelometer as the better measure of light scattering, bias by this criterion better addresses the question of algorithm performance with regards to the haze conditions. Criterion 2 uses the algorithm-estimated light extinction to determine which sample periods were in each quintile. The Regional Haze Rule index is based on the highest and lowest haze levels as determined by the algorithm, so criterion 2 better addresses the haze rule application of the algorithm. Tables 2 through 5 show the bias results by both criteria for the current and new algorithm for sites averaged by RPO.

Table 2. Averaged fractional bias by RPO for the current IMPROVE algorithm with quintiles based on measured light scattering (criterion 1). Bold font highlights the bias values that are lower than corresponding values in Table 3.

RPO	Quintile 1	Quintile 2	Quintile 3	Quintile 4	Quintile 5	Average
CEN	0.67	0.18	0.10	**0.02**	-0.11	0.17
MANE	0.93	0.27	0.19	0.10	**0.01**	0.28
VISTAS	0.59	0.21	0.11	**0.02**	-0.13	0.16
WRAP	1.07	0.37	0.18	0.07	**-0.08**	0.32

Table 3. Averaged fractional bias by RPO for the current new proposed algorithm with quintiles based on measured light scattering (criterion 1). Bold font highlights the bias values that are lower than corresponding values in Table 2.

RPO	Quintile 1	Quintile 2	Quintile 3	Quintile 4	Quintile 5	Average

These tables show that the new algorithm has lower fractional bias than the current IMPROVE algorithm in all but the haziest conditions (i.e. quintile 5) regardless of the criterion used to sort the data into quintiles. By criterion 1, the two algorithms perform about the same for haziest days except for the sites in the southeastern U.S. (i.e. the VISTA RPO), where the new algorithm has much lower bias (1% compared to 13%). Using criterion 2, the current algorithm has consistently lower bias compared with the new algorithm for the haziest days (i.e. quintile 5) for each of the RPOs. This seeming paradox is the result of the somewhat greater imprecision of the new algorithm compared to the current algorithm, which results in somewhat larger errors in selecting worst haze sample periods for the new algorithm compared with the current algorithm.

Scatter plots (Figures 1 and 3) of light scattering estimates from the current and new proposed algorithms versus nephelometer data for all available data at 21 monitoring sites are one way to view the overall performance differences between the two. These figures show that the bias at the extremes is reduced using the new algorithm compared to the original IMPROVE algorithm (i.e. the points tend to be better centered on the one-to-one line). They also show that the somewhat reduced precision of the new algorithm compared to the original IMPROVE algorithm (i.e. points are more broadly scattered).

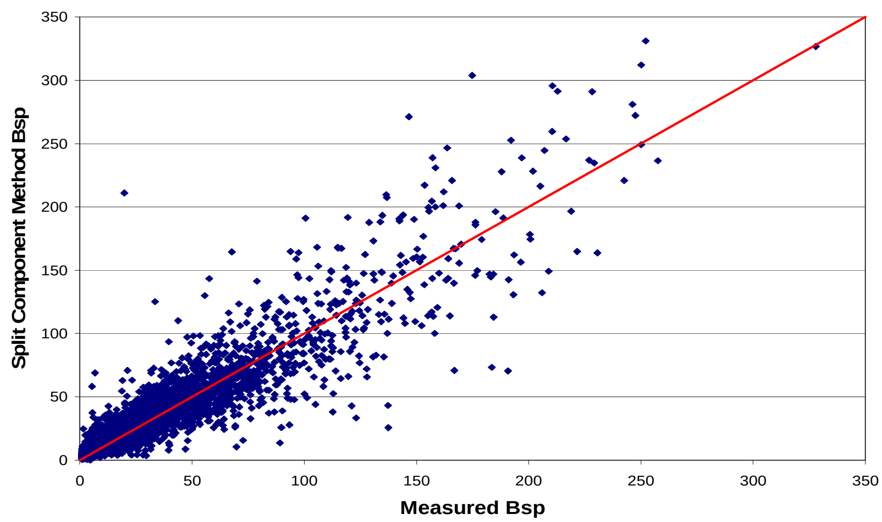

Figure 2. Scatter plot of the recommended revised algorithm estimates of light scattering versus measured light scattering.

Similar pairs of scatter plots were prepared for each individual monitoring site (available in the appendix). Figures 4 and 5 are example plots for Shenandoah and Grand Canyon National Parks. The logarithmic scales on these plots exaggerate the scatter for low values compared to high values. The individual-site scatter plots have the 80th percentile values indicated on the graphs for the predicted and measured values by horizontal and vertical lines respectively. Points that are to the right of the vertical line have nephelometer values that are among the 20% worst light scattering for that monitoring sites. Points that are above the horizontal line have algorithm determined values that are among the 20% worst estimated light scattering for that monitoring site.

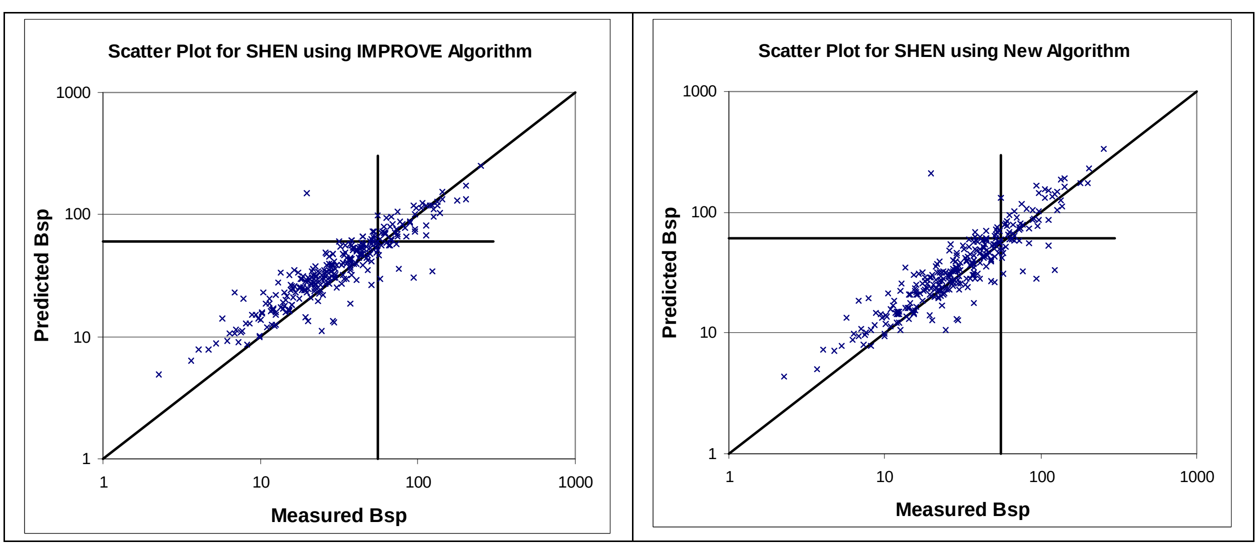

Figure 4. Scatter plots of the current IMPROVE and new recommended algorithm estimates of light scattering versus measured light scattering for Shenandoah National Park. Horizontal and vertical lines are at the 80th percentile for estimated and measured light scattering.

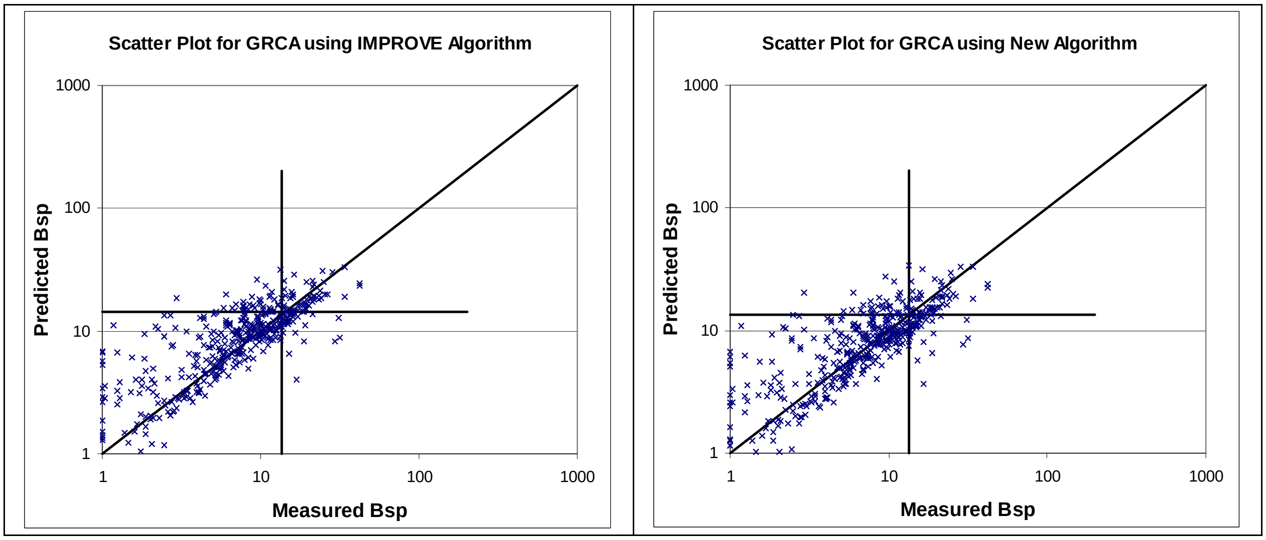

Figure 5. Scatter plots of the current IMPROVE and new recommended algorithm estimates of light scattering versus measured light scattering for Grand Canyon National Park. Horizontal and vertical lines are at the 80th percentile for estimated and measured light scattering.

The proposed new algorithm performs noticeably better with respect to having data points more centered on the one-to-one line at the high and low haze level extremes than the current IMPROVE algorithm for Shenandoah National Park, which is typical for the high haze level locations in the southeast U.S. A large number of the measured worst haze sample periods are correctly identified by both algorithms (these are the points above and to the right of the two 80th percentile lines). The differences between the two algorithms for Grand Canyon National Park and most of the other less hazy locations are not apparent in these scatter plots.

The final approach for evaluating the relative performance of the two algorithms is to compare the average composition of the best haze days and the worst haze days as selected using each algorithm and using the measured light scattering. Table 6 and 7 contain the average composition by RPO for days selected as best and worst by these three methods. Similar results for each of the 21 nephelometer monitoring locations are shown in tables in the appendix.

Table 6. Mean light scattering and percent $PM_{2.5}$ composition for the five major components for 20% best days as determined by measurement, the current IMPROVE algorithm and the proposed new algorithm.

RPO		Mean Bsp (Mm-1)	Percent Ammonium Sulfate	Percent Ammonium Nitrate	Percent OCM	Percent Soil	Percent Coarse	Percent EC

	NEW	33	13	6	27	6	44	3

These tables demonstrate that the composition associated with the best and worst haze days are not very sensitive to the method of identifying the sample periods that fit in best and worst categories. Some of the individual sites (e.g. Grand Canyon) have somewhat larger variations in the composition between measurement-selected days compared to algorithm-selected days, though there's little difference between the average composition comparing the two algorithms on the best and worst days. The contributions to light extinction by the various components were not explicitly calculated, but are inherently somewhat different because of the explicit differences in the two algorithms.

In summary, the proposed new algorithm for estimating haze reduces the biases compared to measurements at the high and low extremes. This is most apparent for the hazier eastern sites. The composition of days selected as best and worst by the current and the new algorithm are very similar, and similar to days selected by measurements. Most of the reduction of bias associated with the new algorithm is attributed to the use of the split component extinction efficiency method for sulfate, nitrate and organic components that permitted variable extinction efficiency depending on the component mass concentration. Though not subject to explicit performance testing, the proposed new algorithm also contains specific changes from the current algorithm that reflect a better understanding of the atmosphere as reflected in the more recent scientific literature (e.g. change to 1.8 from 1.4 for organic compound mass to carbon mass ratio) and a more complete accounting for contributors to haze (e.g. sea salt and NO_2 terms), and use of site specific Rayleigh scattering terms to reduce elevation-related bias.

I. INTRODUCTION

A. Overview

This report documents the data sources, methods, and results for preparing the 2002 base year criteria air pollutant (CAP) and ammonia (NH_3) emissions inventories for point, area, and nonroad sources for the Central Regional Air Planning Association (CENRAP) Regional Planning Organization (RPO). The CENRAP region includes the states and tribal jurisdictions of Arkansas, Iowa, Kansas, Louisiana, Minnesota, Missouri, Nebraska, Oklahoma, and Texas. CENRAP (and other RPOs) will use these inventories to support air quality modeling, State Implementation Plan (SIP) development, and implementation activities for the regional haze rule and fine PM and ozone National Ambient Air Quality Standards (NAAQS).

The inventories and supporting data prepared include the following:

(1) Comprehensive, county-level, mass emissions and modeling inventories for point, area, and nonroad sources of 2002 emissions for the CAPs and NH_3 for the State, Local, and Tribal (S/L/T) agencies included in the CENRAP region;
(2) The temporal, speciation, and spatial allocation profiles for the CENRAP region inventories; and
(3) Inventories for other RPOs, Canada, and Mexico.

The mass emissions inventory files were prepared in the National Emissions Inventory (NEI) Input Format Version 3.0 (NIF 3.0). The modeling inventory files were prepared in the Sparse Matrix Operator Kernel Emissions/Inventory Data Analyzer (SMOKE/IDA) format. Ancillary files (holding spatial, temporal, and speciation profile data) were prepared in SMOKE/IDA compatible format.

The inventories include annual emissions for sulfur dioxide (SO_2), oxides of nitrogen (NO_x), volatile organic compounds (VOC), carbon monoxide (CO), NH_3, and particles with an aerodynamic diameter less than or equal to a nominal 10 and 2.5 micrometers (i.e., primary PM_{10} and $PM_{2.5}$). The inventories included summer day, winter day, and average day emissions. However, not all agencies included daily emissions in their inventories, and, for the agencies that did, the temporal basis for the daily emissions varied between agencies. Consequently, the inventories did not contain a complete and consistent set of daily emissions for all source categories and pollutants. Therefore, daily emissions prepared by S/L/T agencies were maintained in the NIF files if they met quality assurance (QA) review requirements. However, CENRAP requested that the daily emissions not be included in the SMOKE input files. The temporal profiles prepared for this project will be used to calculate daily emissions. If needed, the daily emissions prepared by the agencies may be retrieved from the NIF database files.

The consolidated inventories were prepared using the inventories that S/L/T agencies submitted to the United States (U.S.) Environmental Protection Agency (EPA) from May through July of 2004 as a requirement of the Consolidated Emissions Reporting Rule (CERR). The EPA's format and content QA programs (and other QA checks not included in EPA's QA software) were run on each inventory to identify format and/or data content issues (EPA, 2004a).

E.H. Pechan & Associates, Inc. (Pechan) and the University of North Carolina, Chapel Hill – Carolina Environmental Program (UNC-CEP) worked with the CENRAP's Emission Inventory (EI) Workgroup and the S/L/T agencies to resolve QA issues and augment the inventories to fill data gaps in accordance with the Methods Plan and Quality Assurance Project Plan (QAPP) prepared for this project (CENRAP, 2004a; CENRAP, 2004b). The EI Workgroup and S/L/T agencies reviewed the draft inventory and ancillary files from December 2004 through February 2005. The inventories and SMOKE input files were revised to incorporate the review comments.

B. Summary of the 2002 Base Year Inventories

This section of the report provides a brief summary of the consolidated 2002 base year inventories for the CENRAP region. Table 1 shows total annual emissions for CAPs and NH_3 for point, area, nonroad, and onroad sources. The sector contributing the highest emissions varies by pollutant. Point sources account for the highest percentage of total NO_x (36%) and SO_2 (87%) emissions. Area sources account for the highest percentage of total VOC (50%), primary PM_{10} (PM10-PRI (93%)), primary $PM_{2.5}$ (PM25-PRI (81%)), and NH_3 (86%) emissions. Onroad sources account for the highest percentage of CO (53%) emissions. Onroad and nonroad sources each account for 18% of total VOC emissions. Onroad sources account for 29% and nonroad sources account for 19% of total NO_x emissions.

Table 2a shows total annual emissions by state/tribe and pollutant for all four sectors combined. Tables 2b through 2e show total annual emissions by state/tribe and pollutant for area, point, nonroad, and onroad sources, respectively. Tables A-1 through A-6 in Appendix A provide summaries of annual emissions by source category and sector for VOC, NO_x, CO, SO_2, PM10-PRI and PM25-PRI, and NH_3, respectively. The emissions in each table are sorted in descending order with the highest emitting categories listed at the top of the table. The tables also show annual emissions as a percentage of total emissions from all sectors, and the cumulative percentage contribution. Chapter III of this report identifies additional summaries of emissions, including county-level summaries that contain the data source codes that identify the origin and year of emissions data.

In addition to the CAPs and NH_3, emissions for carbon dioxide (CO_2), methane (CH_4), elemental carbon (EC), organic carbon (OC), total primary and filterable particulate matter (PM-PRI/-FIL), filterable PM-10 (PM10-FIL), and filterable $PM_{2.5}$ (PM25-FIL) were carried in the mass emissions inventory files. However, these pollutants are not included in the summaries since the emissions for these pollutants were not consistently reported by all S/L/T agencies for a given sector. In addition, AR included wind-blown fugitive dust emissions in its area source inventory, and some but not all S/L/T agencies included NH_3 emissions associated with natural sources (e.g., domestic and wild animals) in their area source inventories. These emissions were kept in the area miscellaneous sources inventory, and are included in the sector-level summaries (as geogenic and natural/biogenic sources) described in Chapter III of this report.

C. Organization of the Report

In Chapter II of this report, section A provides an introduction to the chapter and sections B through D present the data sources and methods applied to prepare the mass emissions inventory and SMOKE input files for point, area, and nonroad sources within the CENRAP region.

Section E explains the data sources and methods applied to prepare 2002 Continuous Emissions Monitoring (CEM) data for the entire CENRAP modeling domain in the SMOKE and the RPO data exchange protocol formats. Section F explains the data sources and methods for developing temporal, speciation, and spatial allocation profiles for the point, area, and nonroad source categories included in the CENRAP region inventories. Section G provides documentation of the SMOKE and RPO data exchange protocol files prepared under this project.

Chapter III and Appendix A provide summaries of the 2002 emissions inventories for point, area, nonroad, and onroad sources within the CENRAP region. Chapter IV identifies the inventory and supporting data files compiled for areas outside of the CENRAP region, and Chapter V provides the references for this report.

II. CRITERIA AIR POLLUTANT AND NH_3 INVENTORIES FOR THE CENRAP REGION

A. Introduction

The inventory data were taken from the following sources in priority order:

a. The inventories that S/L/T agencies submitted to EPA from May through July 2004;
b. Supplemental data supplied by the S/L/T agencies (e.g., data that have been finalized or revised after an agency submitted its inventory to EPA);
c. Inventories developed by CENRAP; and
d. The 2002 preliminary NEI.

Table 3 provides a summary of the S/L/T point, area, and nonroad source inventories that the S/L/T agencies submitted to EPA. The EPA performed some limited QA review of the S/L/T inventories to identify format, referential integrity, and duplicate record issues. The EPA revised the inventories to address these issues and made the files available to the S/L/T agencies on August 6, 2004. These inventory files were used as the starting point for the CENRAP inventory. Pechan then performed QA review of the inventories to identify (1) remaining QA issues that needed to be resolved through consultation with the EI Workgroup, and (2) missing data that needed to be added to the inventories to support air quality modeling studies.

Table 3. Summary of 2002 Inventories that S/L/T Agencies Submitted to EPA [1]

State/Local/Tribal Agency	Point	Area	Commercial Marine Vessels	Railroad Locomotives	Aircraft
AR	x	x	x	x	x
IA	x	x[3]			
KS	x[2]	x[3]		x[3]	
LA	x	x[3]		x[3]	
MN	x[2]	x		x	x[4]
Fond du Lac Band of the Minnesota Chippewa Tribe	x	x			
MO	x[2]	x[3]		x[3]	
NE-State	x	x			
NE-Lincoln (Lancaster County)	x	x			
NE-Omaha (Douglas County)	x				
OK	x	x			
TX	x	x	x	x	x

[1] An “x” identifies the sector for which a S/L/T agency submitted a CAP inventory to EPA.
[2] State submitted separate inventories for the criteria air pollutants and NH_3.
[3] State submitted only an NH_3 inventory.
[4] State included its inventory for commercial and military aircraft and auxiliary power units in its point source inventory.

After resolving the QA issues, the files were updated to revise or add data provided by the S/L/T agencies. Inventories developed by CENRAP were added to the inventories as directed by the S/L/T agencies. Then, the inventories were compared to the 2002 preliminary NEI to identify

categories that existed in the NEI but not the S/L/T inventories. The NEI data were added to the S/L/T inventories as directed by the EI Workgroup.

The following sections B, C, and D provide the methods for preparing the consolidated emissions inventories for point, area, and nonroad sources, respectively. Each section discusses the QA review that was conducted on the S/L/T inventories to identify QA issues that were corrected to support air quality modeling. Then, each section discusses the augmentation procedures that were applied to fill in missing data. These procedures identify supplemental data that S/L/T agencies provided to add to or replace data in their inventories, the CENRAP-sponsored inventories that were added to the inventories as approved by the S/L/T agencies, and the 2002 NEI categories that S/L/T agencies requested to be added to their inventories. The augmentation procedures also explain how missing PM emissions were estimated and added to the inventories after incorporating inventory data supplied by S/L/T agencies, the CENRAP-sponsored inventory data, and data from the 2002 NEI.

For point sources that are subject to CEM requirements, section E discusses the data sources and procedures for preparing the 2002 CEM data and temporal profiles to support air quality modeling. For point, area, and the non-NONROAD model source categories, Section F discusses the data sources and procedures for preparing temporal, speciation, and spatial allocation profiles needed to support air quality modeling. Section G discusses the formats in which the final emissions, temporal, speciation, and allocation data were prepared.

B. Point Source Inventory Methods

1. Data Sources

For each S/L/T inventory submitted to EPA, Table 4 provides a summary of the pollutants included in each inventory, and compares the number of counties in the inventory to the number of counties in the 2002 preliminary NEI and in each S/L/T agency. The table also compares the number of facilities in the S/L/T inventory to the number of facilities in the 2002 preliminary NEI.

The inventories obtained from EPA are in Access 2000 databases in NIF 3.0. Each inventory was loaded into an Oracle database in NIF 3.0 to combine the inventories into a single data set. Then, after loading the inventories into Oracle in NIF 3.0, the following updates were performed on the consolidated data set, if necessary:

Table 4. Summary of Pollutants, Number of Counties, and Number of Facilities in Point Source Inventories

State/Local/ Tribal Agency	CO	NH_3	NO_x	PM-PRI	PM10-PRI	PM25-PRI	PM10-FIL	PM25-FIL	PM-CON	SO_2	VOC	Number of Counties in 2002 S/L/T Inventory	Number of Counties in 2002 Preliminary NEI	Number of Counties in State	Number of Facilities in 2002 S/L/T Inventory	Number of Facilities in 2002 Preliminary NEI
AR	x	x	x							x	x	57	60	75	227	324
IA	x	x	x	x	x	x				x	x	74	26	99	270	67
KS[1]	x	x	x		x	x	x	x		x	x	97	96	105	708	705
		x										104	16	105	3,319	20
LA	x	x	x				x	x		x	x	59	60	64	906	1,033
MN[1]	x	x	x		x	x		x		x	x	87	82	87	2,628	836
		x										77	13	87	542	14
Fond du Lac Band of the Minnesota Chippewa Tribe	x		x	x	x					x	x	NA[2]	NA	NA	5	NA
MO[1,3]	x	x	x		x					x	x	109	103	115	1,646	720
		x										105	16	115	1,181	20
NE-State	x		x			x				x	x	27	72	93	36	634
NE-Lincoln (Lancaster County)	x		x		x					x	x	1	1	93	17	100
NE-Omaha (Douglas County)	x	x	x	x	x	x				x	x	1	1	93	68	87
OK	x	x	x	x	x	x				x	x	66	69	77	397	1,046
TX	x		x		x	x				x	x	201	203	254	1,914	3,268

[1]State submitted separate inventories for the criteria pollutants and NH_3. The NH_3 inventory was prepared under a CENRAP-sponsored project. The number of counties and facilities in the 2002 preliminary NEI are for facilities with annual NH_3 emissions. Note that the number of counties and facilities with annual NH_3 emissions in KS and MO in the 2002 preliminary NEI are the same.

[2] NA = Not Applicable.

[3] The data for MO are from its original inventory submittal to EPA.

- Hazardous air pollutant (HAP) records were removed since the inventory will support regional haze, fine PM, and ozone modeling.

- Pollutant codes were corrected to make them NIF 3.0 compliant (e.g., update PMPRI pollutant code to PM-PRI). Additionally, other codes were identified for remediation on a case-by-case basis.

- Records with a submittal flag indicating deletions (submittal_flag = 'D' or 'RD') were removed from the inventory.

- Null values in the tribal code field were updated to '000' since this field is a part of the data key that defines records as unique in all eight NIF tables.

- The following NIF plus fields were added to the Transmittal (TR), Site (SI), Emission Unit (EU), Emission Release Point (ER), Emission Process (EP), Emission Period (PE), Emission (EM), and Control Equipment (CE) tables:

  - Data Source Codes:

Code	**Description**
S	State agency-supplied data.
L	Local agency-supplied data.
R	Tribal agency-supplied data.
P	Regional Planning Organization.
SC	S/L/T agency Corrected.
AUG-A	PM Augmentation: ad-hoc change.
AUG-C	PM Augmentation: standard augmentation method.
AUG-O	PM Augmentation: set PMxx-FIL = PMxx-PRI where for SCCs starting with 10 (external fuel combustion) and 20 (internal fuel combustion). Note: emission factors and particle-size data for estimating condensible emissions for fuel combustion SCCs starting with 30 were not available; therefore, condensible emissions were not estimated for these processes if an agency provided filterable and not primary emissions for these processes.
AUG-Z	PM Augmentation: automated fill-in of zero values where all PM for a particular process is zero.
GENPARENT	Data source where a parent record was system generated.

  - Revision Date: This field indicates the month and year during which the last revision was made to a record.

  - State Federal Information Processing Standard (FIPS): This field indicates the state FIPS code of the submittal.

  - County FIPS: This field indicates the county FIPS code of the submittal.

- The following NIF plus fields were added to the EM table:

    - Emission Ton Value: This field indicates the values of the emissions in tons. This field was used to prepare summaries of emissions on a consistent emission unit basis.

    - Emission Type Period: This field indicates the period of the Emission Type – either ANNUAL or NONANNUAL. This field was used to prepare summaries of annual emissions.

    - CAP_HAP: This field identifies records for CAP versus records for HAPs. For the CENRAP inventory, the flag is CAP for all records.

    - Year: This field indicates the year of the data; for this inventory, it is 2002.

2. QA Review

QA review on the inventories was conducted in accordance with the QA procedures specified in the QAPP for this project (CENRAP, 2004b). The following discusses the QA diagnoses that were run on the consolidated point source inventory data set. The QA issues identified were communicated to the S/L/T agencies through a set of QA Summary Reports in Excel Workbook files. The agencies provided corrections to the data in the Excel files and the inventory was updated with the corrections.

a. County and Facility Coverage

S/L/T agencies for which the number of counties in their point source inventory submittal to EPA declined relative to the number of counties in the NEI include AR (-3 counties), LA (-1 parish), OK (-3 counties), TX (-2 counties), and NE (-45 counties) (see Table 2). NE moved its small point sources from its area source inventory to its point source inventory; therefore, this increased the county coverage in its point source inventory. States for which the number of counties in their point source inventory submittal to EPA increased relative to the number of counties in the NEI included IA (+48 counties), MO (+6 counties), MN (+5 counties), and KS (+1 county). The NEI did not contain any tribal data for the CENRAP region.

As shown in Table 4, the number of facilities included in the inventories for AR, LA, NE, NE – Omaha, NE – Lincoln, OK, and TX is lower than the number of facilities included in the 2002 preliminary NEI. An electronic match was conducted on the state and county FIPS and facility identification (ID) code between the two inventories to identify facilities and their emissions in the 2002 preliminary NEI but not in the S/L/T agency inventories. However, due to changes that S/L/T agencies made to facility ID codes in their inventories, the electronic matching did not work well as this procedure identified facilities that are in both inventories but with different facility ID codes. The results of this comparison were provided to the agencies for review and all of the agencies confirmed that there were no missing facilities in the point source inventories they submitted to EPA.

b. Pollutant Coverage

As shown in Table 4, all of the S/L/T inventories contain emissions for CO, NO_x, SO_2, and VOC. The inventories for TX; NE state; Lancaster County, NE; and the Fond du Lac Band of the Minnesota Chippewa Tribe did not include NH_3 emissions. KS, MN, and MO submitted NH_3 inventories prepared under a CENRAP-sponsored project. These NH_3 inventories were merged with the CAP inventories for these three states. Pechan worked with these three agencies to resolve facility matching and duplicate records that occurred in the Transmittal (TR), Site (SI), Emission Release Point (ER), Emission Unit (EU), and EP tables.

Except for AR, all S/L/T agencies included one or more forms of PM, PM_{10}, and/or $PM_{2.5}$ in their inventories. AR subsequently provided a new inventory that included PM_{10} and $PM_{2.5}$ emissions data. The modeling inventory needs to include a complete set of PM10-PRI and PM25-PRI pollutants for all sources of PM_{10} and $PM_{2.5}$. Therefore, based on the data the S/L/T agencies included in their inventories, procedures were developed and applied to fill in missing pollutant data needed to prepare a complete PM10-PRI and PM25-PRI inventory. The QA review of the PM data is discussed further in the following section, and the augmentation procedure is discussed in section II.B.4.

c. Particulate Matter (PM) Emissions Consistency and Completeness Review

The following consistency checks were performed at the EM table data key level (for annual emissions) to compare PM emissions:

- If a process was associated with a PM emission record, but was missing one or more of the following (as appropriate for the Source Classification Code [SCC] [i.e., condensible PM (PM-CON) is associated with fuel combustion only]): PM10-FIL, PM10-PRI, PM25-FIL, PM25-PRI, or PM-CON, the record was flagged for review.

- The following equations were used to determine consistency:

  PM10-FIL + PM-CON = PM10-PRI
  PM25-FIL + PM-CON = PM25-PRI
  PM-FIL + PM-CON = PM-PRI (as appropriate)

- The following comparisons were applied to determine consistency:

  PM10-PRI >= PM10-FIL
  PM25-PRI >= PM25-FIL
  PM10-PRI >= PM-CON
  PM25-PRI >= PM-CON
  PM10-FIL >= PM25-FIL
  PM10-PRI >= PM25-PRI
  PM-PRI >= PM10-PRI (as appropriate)
  PM-PRI >= PM25-PRI (as appropriate)

PM-FIL >= PM10-FIL (as appropriate)
PM-FIL >= PM25-FIL (as appropriate)

If the data failed one of these checks it was diagnosed as an error. If a S/L/T agency did not provide corrections to these errors, the errors were corrected/filled in according to the augmentation procedure discussed in section II.B.4.

d. Emission Release Point (ERP) Coordinate Review

Location coordinates for point sources were evaluated using geographic information system (GIS) mapping to determine if the coordinates were within 0.5-kilometers of the boundary of the county in which the source was located. If not, the S/L/T agency was asked to review the coordinates and provide corrections to either the coordinates or the state and county FIPS codes. The 0.5-kilometer test resulted in a large number of ERPs for review by the agencies. Therefore, to assist S/L/T agencies in prioritizing their review of coordinates, ERP records with coordinates located more than 0.5, 1, 2, 3, 5, 7, and 10 or more kilometers from their county boundary, and coordinates that mapped outside of their state boundary were identified. Annual emissions summed to the ERP level were included in the QA Summary Report to identify records with zero emissions for all pollutants and to identify the highest emitting stacks.

e. ERP Parameter Review

The EPA's QA guidance for diagnosing ERP issues for the point source NEI (EPA, 2004b) was applied to identify QA issues in the S/L/T point source inventories. The QA guidance involved diagnosing the correct assignment of the ERP type (i.e., stack or fugitive), parameters with zero values, parameters not within the range of values specified in the EPA's QA procedures, and consistency checks (i.e., comparing calculated values against expected values). In many cases errors were due to defaulted zeros, and submitting agencies were requested to provide the value. In other cases, out-of-range errors were caused by unit conversion issues (e.g., stack parameters were in ft, ft/sec, cu ft/sec or degrees Fahrenheit). The agencies were asked to provide corrections or additions to ERP parameters, or note in the QA Summary Report that records flagged with potential QA issues were corrected. If an agency did not provide corrections for out-of-range or missing values, the data were corrected or filled in according to the ERP augmentation procedure discussed in section II.B.4.

f. Control Device Type and Control Efficiency Data Review

The CE codes in the "Primary Device Type Code" and "Secondary Device Type Code" fields were reviewed to identify invalid codes (i.e., codes that did not exist in the NIF 3.0 reference table) and missing codes (e.g., records with a null or uncontrolled code of 000 but with control efficiency data).

QA review of control efficiency data involved diagnosis of two types of errors. First, records were reviewed to identify control efficiency values that were reported as a decimal rather than as a percent value. Records with control efficiencies with decimal values were flagged as a

potential error (although not necessarily an error, since the real control efficiency may be less than 1 percent).

The second check identified records where 100% control was reported in the CE table, but the emissions in the EM table were greater than zero and the rule effectiveness value in the EM table was null, zero, or 100% (implying 100 percent control of emissions). Because many agencies did not populate the rule effectiveness field or a default value of zero was assigned, records with null or zero rule effectiveness values were included where the CE was 100% and emissions were greater than zero. For records that met these criteria, the records were reviewed by the S/L/T agency to provide corrections, if necessary.

g. Start and End Date Checks

QA review was conducted to identify start date and end date values in the PE and EM tables to confirm consistency with the inventory year in the transmittal table, and to confirm that the end date reported is greater than the start date reported.

h. Annual and Daily Emissions Comparison

The following QA checks were conducted to identify potential errors associated with the incorrect reporting of daily and/or annual emissions:

- Any "DAILY" type record that is greater than its associated "ANNUAL". Only TX and MO sent DAILY records. While TX did have DAILY records greater than annual (due to the TX original database rounding of TON vs. LB records). For the CENRAP point source inventory it was determined that the most efficient approach was to use only the ANNUAL records.

3. Responses from S/L/T Agencies

The point source inventories were revised to incorporate the corrections that the S/L/T agencies provided in response to the QA issues identified in their inventories. Where responses from the S/L/T agencies were not provided, standard procedures were used to default or augment the data. Section II.4 describes in more detail the gap filling and augmentation procedures. Additionally, included with this report is a set of S/L/T-specific files indicating responses to specific QA issues and defaults that were implemented with remaining QA issues. An example of a default implemented would be the correction of TONS to TON in a unit field. Each S/L/T set of files is accompanied by a Read_me.txt file that describes the files in further detail. The files included with each S/L/T documentation set (if the QA issue existed) are the following (based on the QA Issues discussed above):

- PM Augmentation QA Summary
- PM Augmentation Preliminary Review
- Stack Parameter QA Summary
- Stack Coordinates QA Summary
- Stack Parameter and Coordinate Augmentation

- SCC QA Summary
- Control Device/Efficiency Summary

In addition, the listing of state QA files also includes the output of the EPA QA checker as run on the final CENRAP inventory, and the PM ratio factor table (as described in section II.B.4.b) as developed for the CENRAP SCC and control devices.

4. Gap Filling and Augmentation

The following discusses the augmentation procedures that were used to fill in missing data that were not supplied by the S/L/T agencies.

a. CENRAP Sponsored Inventories

The CENRAP inventory includes data generated from CENRAP sponsored source type oriented inventories. The following inventories (and the relevant S/L/T agencies) were included with the CENRAP inventory:

- CENRAP NH_3 Inventory (IA, KS, MO, MN, NE, OK)
- MN Fires Inventory (MN)
- CENRAP Prescribed Burning Inventory (all states)
- CENRAP Concentrated Animal Feeding Operations (CAFO) Dust Inventory (all states)

b. PM Augmentation

The PM augmentations process gap-fills missing PM pollutant complements. For example, if a S/L/T agency provided only PM10-PRI pollutants the PM augmentation process filled in the PM25-PRI pollutants. The steps in the PM augmentation process were as follows:

- Initial QA and remediation of S/L/T provided PM pollutants;
- Development of PM factor ratios based on factors from FIRE (Factor Information REtrieval) version 6.2 and the PM Calculator (EPA, 2003; EPA, 2004c);
- Implementation of the ratios developed in step 2.; and
- Presentation of PM augmentation results to S/L/T agencies for review and comment

Note: There are two Access databases that accompany this documentation. The first database is the *Reference Tables for PM Augmentation*. This database contains the SCC Control Device Ratio table, the Emission Factors table and Emission Factors Crosstab table discussed in Step 2. The PM Calculator ratio table can be provided upon request – it contains all possible combinations for SCC and Control Device types that are available in the PM Calculator.

An additional database (*PM Augmentation Draft*) that contains the PM crosstab table with the preliminary PM Augmentation results and a QA table (which may be empty) was provided. This database will be discussed in Step 3 and Step 4.

These steps are further detailed below.

1. Initial QA and Remediation of PM Pollutants

S/L/T agencies were initially presented with files that detailed potential inconsistencies and missing information in their PM pollutant inventory. Inconsistencies in PM pollutants include the following:

- PM-PRI less than PM10-PRI, PM25-PRI, PM10-FIL, PM25-FIL, or PM-CON
- PM-FIL less than PM10-FIL, PM25-FIL
- PM10-PRI less than PM25-PRI, PM10-FIL, PM25-FIL or PM-CON
- PM10-FIL less than PM25-FIL
- PM25-PRI less than PM25-FIL or PM-CON
- The sum of PM10-FIL and PM-CON not equal to PM10-PRI
- The sum of PM25-FIL and PM-CON not equal to PM25-PRI

Potential missing information was summarized in a table which detailed the variety of cases provided by the S/L/T agency. For example, a S/L/T agency might have provided PM10-FIL and PM25-FIL for some processes, but for other processes only PM10-FIL was provided.

S/L/T agencies were asked to review this information and provide corrections where possible. In general, corrections (or general directions) were provided in the case of the potential inconsistency issues. An example of a general direction provided by a S/L/T agency was to remove PM25-FIL where greater than PM10-FIL because the PM10-FIL was (in their particular case) known to be more reliable. In other cases, the agency-provided specific process level pollutant corrections. In general, if specific direction was not provided by the agency, priority was given to the PM_{10} number.

2. Development of PM Factor Ratio

The primary deliverable of this step of the process was the development of a table keyed by SCC, primary control device, and secondary control device. This table is called the SCC Control Device Ratios table. The table structure follows the discussion below.

This table was filled according to the following steps:

- Ratios (both condensible and noncondensible) were added from FIRE for SCCs starting with 10* (external fuel combustion) and 20* (internal fuel combustion) where there was a direct match between the provided SCC, and primary and secondary control devices.
- Ratios (non-condensable) were added from the PM Calculator for SCCs starting with 10* and 20* where there was not a direct match between the provided SCC, and primary and secondary control devices. Condensible ratios were added from the PM Calculator based on the uncontrolled SCC for these SCCs. In some cases, it was necessary to map the SCC and control devices to the PM calculator to find a match

for the noncondensible ratios. In some cases, it was necessary to map the SCC to FIRE to find a match for condensible ratios.

Table 5. Description of the Field Names and Descriptions for the SCC Ratio Table

Field Name	Field Description
PM Calculator	A “Yes” in this field indicates that at least some of the information was retrieved from the PM Calculator
FIRE	A “Yes” in this field indicates that at least some of the information was retrieved from the Emission Factors table. A “Condensible Ratios” in this field indicates that the condensible ratios factors were retrieved from this table.
Other	A field to indicate other sources as necessary.
SCC	Source category code from the S/L/T agency-provided data.
SCC_DESC	Description of source category code from the S/L/T agency-provided data.
maptoSCC	This field equals SCC unless the SCC provided was not found in the appropriate source table. In that case, the SCC was mapped using the closest available appropriate mapping choice.
maptoSCC_DESC	Description of the maptoSCC.
mapSCCNote	Any notes related to the mapping of the SCC. A “Yes” in this field indicates that the SCC was mapped.
PD	Primary device type from the S/L/T agency provided data.
PD_DESC	Description of the primary device (PD).
maptoPD	This field equals PD unless the PD provided was not found in the appropriate source table. In that case, the PD was mapped using the closest available appropriate mapping choice.
maptoPD_DESC	Description of the maptoPD.
mapPDNote	Any notes related to the mapping of the PD. A “Yes” in this field indicates that the PD was mapped.
SD	Secondary device type from the S/L/T agency provided data.
SD_DESC	Description of the secondary device (SD).
maptoSD	This field equals SD unless the SD provided was not found in the appropriate source table. In that case, the SD was mapped using the closest available appropriate mapping choice.
maptoSD_DESC	Description of the maptoSD.
mapSDNote	Any notes related to the mapping of the SD. A “Yes” in this field indicates that the SD was mapped.
PM-FIL/PM10-FIL	This field and the following are ratios calculated from emission factors found either in FIRE or the PM calculator.
PM-FIL/PM25-FIL	This field and the following are ratios calculated from emission factors found either in FIRE or the PM calculator.
PM-FIL/PM-PRI	This field and the following are ratios calculated from emission factors found either in FIRE or the PM calculator.
PM-PRI/PM10-PRI	This field and the following are ratios calculated from emission factors found either in FIRE or the PM calculator.
PM-PRI/PM25-PRI	This field and the following are ratios calculated from emission factors found either in FIRE or the PM calculator.
PM10-FIL/PM25-FIL	This field and the following are ratios calculated from emission factors found either in FIRE or the PM calculator.
PM10-PRI/PM25-PRI	This field and the following are ratios calculated from emission factors found either in FIRE or the PM calculator.
PM-CON/PM10-FIL	Condensible ratios were calculate from FIRE if available for 10* and 20* SCCs. If condensible ratios were not found in FIRE for 10* and 20* these ratios were set to zero.
PM-CON/PM10-PRI	Condensible ratios were calculate from FIRE if available for 10* and 20* SCCs. If condensible ratios were not found in FIRE for 10* and 20* these ratios were set to zero.
PM-CON/PM25-FIL	Condensible ratios were calculate from FIRE if available for 10* and 20* SCCs. If condensible ratios were not found in FIRE for 10* and 20* these ratios were set to zero.
PM-CON/PM25-PRI	Condensible ratios were calculate from FIRE if available for 10* and 20* SCCs. If condensible ratios were not found in FIRE for 10* and 20* these ratios were set to zero.
PM-CON/PM-FIL	Condensible ratios were calculate from FIRE if available for 10* and 20* SCCs. If condensible ratios were not found in FIRE for 10* and 20* these ratios were set to zero.
PM-CON/PM-PRI	Condensible ratios were calculate from FIRE if available for 10* and 20* SCCs. If condensible ratios were not found in FIRE for 10* and 20* these ratios were set to zero.
RPO Specific Note	Indicates SCC and control device combinations are in the RPO inventory.
Additional Notes	Any notes regarding assumptions about ratios.

- For natural gas, process gas and liquefied petroleum gas SCCs starting with 10* and 20*, it was assumed (based on FIRE emission factors trend) that the PM-PRI/PM10-PRI/PM25-PRI ratio was equal to 1. It was also assumed that the PM-FIL/PM10-FIL /PM25- FIL was equal to 1. Condensible ratios were calculated from uncontrolled FIRE emission factors based for these SCCs. In some cases it was necessary to map the SCC to FIRE to find a match for condensible ratios.
- Ratios for SCCs not like 10* and 20* were obtained from the PM Calculator. It was assumed that the condensible component was zero.

Accompanying this document is a database containing the SCC Control Device Ratios table. Additionally, the Emission Factors and Emission Factors Crosstab table (which are derived from FIRE) are provided. The Emission Factors Crosstab table contains the ratios developed from the Emission Factors table. The Emission Factors table contains detailed information on the emission factors used to develop the ratios.

Note: Ratios from the PM calculator were developed using a standard input of 100 TONS of uncontrolled PM-FIL emissions.

3. Implementation of the QA Ratios

In order to calculate the additional PM pollutants based on the SCC Control Device ratio table developed in the above step, a crosstab table was created from the EM table based on the following fields:

- State FIPS
- County FIPS
- Tribal Code
- Emission Unit ID
- Process ID
- Start Date
- End Date
- Emission Type
- SCC
- Primary Device Type
- Secondary Device Type

The primary and secondary device type fields were added based on information from the CE table. If control equipment information was not available these fields were defaulted to 000 ("UNCONTROLLED"). In the few cases where there was a conflict between the control devices reported for the same process for PM pollutants (for example, a PM10-PRI is listed as controlled, but PM-PRI did not have control information), the control device type was selected based on the controlled pollutant.

In addition to the fields listed above, the crosstab included the PM emission amounts for the particular process and a field that indicated whether those emissions existed in the inventory. These fields are as follows:

- PM_PRI
- PM_FIL
- PM10_PRI
- PM10_FIL
- PM25_PRI
- PM25_FIL
- PM_CON
- PM_PRI_EXISTS
- PM_FIL_EXISTS
- PM10_PRI_EXISTS
- PM10_FIL_EXISTS
- PM25_PRI_EXISTS
- PM25_FIL_EXISTS
- PM_CON_EXISTS

The emission values are in the PM_PRI, PM_FIL, PM10_PRI, PM10_FIL, PM25_PRI, PM25_FIL, PM_CON fields. The _EXISTS field indicates whether the pollutant was provided by the S/L/T agency. A zero indicates that the pollutant was not provided; a number greater than zero (usually one) indicates that it was provided by the S/L/T agency.

Prior to the development of this crosstab, the EM table was filled in as much as possible using basic assumptions. For example, if the S/L/T agency provided emissions that were equal to zero for PMs for a particular process, it was assumed that all PMs for that process were zero and they were filled in accordingly. Since that assumption was that for non 10* and 20* SCCs, the condensible value was zero – that would lead to PM10-FIL = PM10-PRI and PM25-FIL = PM25-PRI and PM-FIL = PM-PRI. Given that assumption, values for these pollutants were also filled in. After this data insertion, a subset of the crosstab was created. This subset only contained processes that required additional augmentation. The SCC control device type ratio table described in step 2 was based on only those SCC and control device types that required augmentation.

The next step was to fill in the missing information in this crosstab using the information found in the SCC Control Device Ratio table.

In calculating PM complement pollutants, priority was given to calculating –PRI and –CON pollutants. FIL pollutants were only calculated if necessary to calculate other pollutants or if it was a by-product of this calculation.

In augmenting the PM pollutants the non 10* and 20* SCCs were augmented first, with order given to augmenting based on PM_{10} where available, PM_{25} where available, and then PM .

Augmenting the PM pollutants for the 10* and 20* SCCs is more complicated, but the basic approach was to augment based on PM_{10} (FIL or PRI) where available, $PM_{2.5}$ (FIL or PRI) where available, and then PM (FIL or PRI) if PM_{10} or $PM_{2.5}$ variations were not available. Where both PM_{10} (FIL or PRI) and $PM_{2.5}$ (FIL or PRI) variations were both available, the calculation for

PM-CON was generally driven from the PM_{10} number and the complements as necessary were back calculated. Where a –PRI emission factor ratio was required and was not available the –FIL emission factor ratio was used.

After calculations, the data was QA checked to ensure that the calculations resulted in consistent values for the PM complement. On a few occasions, the mix of ratio value and the pollutants and values provided by the S/L/T agency resulted in negative values when –FIL was back-calculated. In this case the negative –FIL value was set to zero and the –PRI value was readjusted.

The resultant PM table has the format described in Table 6.

4. Presentation of PM Augmentation for S/L/T Agencies to Review and Comment

The table described in Step 3 was provided for the S/L/T agency to review in the *PM Augmentation Draft*) . In addition to this table, if there were any remaining QA issues these were listed in the QA table in this database.

Note: There are some high condensible ratios that were calculated for some SCC device type combinations. In most cases these high condensible ratios were the result of the back calculation of PM-CON from PM10-PRI or PM25-PRI records. Since the state had already provided the PMxx-PRI records, these PM-CON values were not added to the inventory.

The data source code field was used to identify records that were added to the inventory to complete the set of PM10-PRI and PM25-PRI emissions.

c. ERP Coordinates

If a S/L/T agency did not provide corrections for ERP coordinates that map more than 5 kilometers outside of the county boundary, or provide coordinates for ERP records that did not have any coordinates in the S/L/T inventory, the following procedures were applied to replace the coordinates:

- Coordinates for other ERPs at the same facility, if available, that map within the county;
- Coordinates for the centroid of the zip code for a facility if a valid zip code is provided or can be obtained from the agency if it is not valid; or
- County centroid coordinates.

Table 6. Description of the Field Names and Descriptions for the Resulting PM Augmentation Table

Field Name	Field Description
Augment	A "Yes" in this field indicates that the process PM was augmented.
Condensible Note	If condensible information was added this field will note that.
STATE_FIPS	State FIPS
COUNTY_FIPS	County FIPS
STATE_FACILITY_IDENTIFIER	Site ID
EMISSION_UNIT_ID	Emission Unit
PROCESS_ID	Process
START_DATE	Start Date
END_DATE	End Date
EMISSION_TYPE	Emission type
SCC	Source Category Code
SCC_DESC	SCC description
PRIMARY_DEVICE_TYPE	Primary Device Type
PRIMARY_DEVICE_TYPE_DESC	PDT description
SECONDARY_DEVICE_TYPE	Secondary Device Type
SECONDARY_DEVICE_TYPE_DESC	SDT description
EMISSION_TYPE_PERIOD	Emission Type Period
EMISSION_RELEASE_POINT_ID	Emission Release Point ID
FACILITY_NAME	Facility Name
ORIS_FACILITY_CODE	ORIS facility Code
SIC_PRIMARY	SIC
ACTUAL_THROUGHPUT	Actual Throughput
THROUGHPUT_UNIT_NUMERATOR	Throughput Unit Numerator
PM_PRI	Emission ton value for PM-PRI
PM_FIL	Emission ton value for PM-FIL
PM10_PRI	Emission ton value for PM10-PRI
PM25_PRI	Emission ton value for PM25-PRI
PM10_FIL	Emission ton value for PM10-FIL
PM25_FIL	Emission ton value for PM25-FIL
PM_CON	Emission ton value for PM-CON
PM_PRI_EXISTS	0 if the S/L/T agency did not provide, > 0 if S/L/T agency did provide
PM_FIL_EXISTS	0 if the S/L/T agency did not provide, > 0 if S/L/T agency did provide
PM10_PRI_EXISTS	0 if the S/L/T agency did not provide, > 0 if S/L/T agency did provide
PM25_PRI_EXISTS	0 if the S/L/T agency did not provide, > 0 if S/L/T agency did provide
PM10_FIL_EXISTS	0 if the S/L/T agency did not provide, > 0 if S/L/T agency did provide
PM25_FIL_EXISTS	0 if the S/L/T agency did not provide, > 0 if S/L/T agency did provide
PM_CON_EXISTS	0 if the S/L/T agency did not provide, > 0 if S/L/T agency did provide
RECORD_COUNT	0 if the S/L/T agency did not provide, > 0 if S/L/T agency did provide
System Update Note	This field contains system codes related to the update queries used to calculate the record.

The zip code was taken from the SI NIF 3.0 table. The zip code was compared to a reference table of valid zip codes to verify that it is an active zip code and exists in the state and county reported in the inventory. If a valid zip code for a facility was not identified, the centroid for the facility's county was used as a last resort. In some cases, the S/L/T agency provided confirmation that the S/L/T coordinates were correct even if the analysis indicated that the coordinates were outside of the county boundary (generally in the case of offshore facilities). These coordinates were not changed. Additionally, all coordinates were converted to latitude/longitude measurements.

d. ERP Parameters

If valid ERP parameters were not provided by the S/L/T agency, Pechan applied the ERP augmentation procedures for the 2002 point source NEI (EPA, 2004b). It has been determined that the augmentation procedures in this document regarding SCC-specific ERP types and temperatures may be difficult to resolve. When this situation occurred, preference was given to the S/L/T agency-supplied ERP type and SCC. For example, the procedures did not account for cases where an emission unit had two processes with one defined as a stack source and the other as a fugitive source. Therefore, the S/L/T-supplied ERP type was used when this situation occurred. If the ERP type was null, and information was not available from the S/L/T agency, the stack height information was used as a guide. If stack height information was available, the ERP was treated as a stack, or, if stack height information was not available, the ERP type was treated as a fugitive. Additionally, there were occasional typographical errors resolved where the ERP type digits were transposed '20' instead of '02'; these were resolved. An additional modification to the augmentation procedure was also implemented. Since, in many cases, null values were filled in with zeros by S/L/T agency databases when comparing out-of-range velocities and flows (after it was determined that the stack and diameter information was correct) – null and zero values were treated in the same manner to prevent inappropriate replacement of stack parameter values. Additionally, stack parameter values were rounded to 1 decimal place when compared to range values (just for the purposes of comparison) to prevent replacement of S/L/T parameter values based on negligible decimal differences.

e. Control Device Type and Control Efficiency Data

Control efficiency values of 100% and rule effectiveness values of 100% with non-zero emissions were diagnosed as potential errors and sent to the S/L/T agencies. Where possible the data were updated with S/L/T corrections. Decimal control efficiencies were also diagnosed and sent to the S/L/T agencies. A decimal control efficiency value usually indicated that the control efficiency was not entered as a percentage value as is required by NIF 3.0. Where possible the data were updated with S/L/T corrections (See Section II.B.2 above).

f. SCC Data

S/L/T agencies were provided with lists of invalid or inactive SCCs. Where the S/L/T agencies were able to provide valid SCC information this was updated with S/L/T agency information. Where S/L/T agencies were unable to provide valid SCC information, the proposed mapping information provided was used to update the S/L/T agency information.

In some cases, the SCC issues were not forthcoming until further into the processing than the initial QA stages. This occurred in cases of late data submissions, and the generation of parent EP records for EM records. In this case, SCCs were replace with the following approach:

- Where the SCC was invalid and mapping was available the SCC was changed to the mapping SCC;
- Where the mapping SCC was not available a more generic code was selected;
- Where the SCC was truncated a generic code was selected;

- Where the SCC was still unavailable the NEI 1999 Version 3 was used as a source;
- Where still unavailable – the most generic of the existing SCCs for the emission unit was used; or
- Where still unavailable – the most generic of the existing SCCs for the facility was used.

This second approach affected 529 records.

g. SIC Data

There were some overall changes made to SIC data – for SICs that had been provided as 0200 these were changed to 02 which is considered a valid SIC by the EPA QA program. Also, in order to provide a better basis for the stack augmentation procedure, missing SIC codes were filled in using the lowest numerical value based on the NAICS to SIC code crosswalk.

5. Revisions to Address Comments

The following items were revised per state instruction during S/L/T agency review of the draft point source inventory:

a. Missouri

Missouri supplied new stack parameter information. Their stack parameters were updated and the stack augmentation procedure was reapplied. The Access database "Missouri_Stack_Updates_200501.mdb" contains the changes.

b. Nebraska-Omaha

NH_3 emissions were revised from 584.78 tons per year to 1.57 tons per year for Nebraska-Omaha facility 0002 - the Omaha Public Power District - North Omaha Power Station.

c. Minnesota

Per Minnesota's request, SCC 30302301 (- crushing) was changed to SCC 30302312 (-pellet induration) for the following facility, emission unit, and processes:

Facility Name: Ispat Inland Mining Company
State Facility ID: 2713700062
Emission Unit ID: EU026
Process IDs: 001, 004, 007, and 010

d. Texas and Missouri Daily Emissions

State daily emissions data for Texas and Missouri are included in the SMOKE input files for the CENRAP inventory. For the NIF 3.0 files, the daily emissions are provided in a file called "CENRAP_Point_Daily_Missouri_Texas_20050216.mdb." A daily emissions record **was**

included in the file only if it had an associated annual emissions record. In addition to the Daily EM and PE records, a table called "Daily Values GT Accompanying Annual Values" was included in the database that lists records with a daily emission value that is greater than the annual emission value. In the overwhelming majority of cases this situation occurred when the daily emission value was very small and recorded in pounds and the annual value was zero and recorded in tons. In many cases, in the originating emission inventory application, emission values are rounded. Therefore, the annual ton value was rounded to zero.

6. QA Review of Final Inventory

Final QA checks were run on the revised point source inventory data set to ensure that all corrections provided by the S/L/T agencies were incorporated into the S/L/T inventories and that there were no remaining QA issues that could be addressed during the duration of the project. After exporting the inventory in Oracle to an Access database in NIF 3.0, the EPA QA program was run on the Access database and the QA output was reviewed to verify that all QA issues that could be addressed were resolved (EPA, 2004a)

This file accompanies this documentation with the specific details included. The following summarizes the remaining QA issues that could not be addressed during the duration of this project (listed by table):

CE

Primary device type codes were not provided by all of the modeled inventories, specifically CAFOs and prescribed burning; it should be determined if there is an appropriate generic primary device type to be used or whether the CE records should be removed.

In the MN prescribed burning inventory, a NIF 3.0 formatting error resulting in a shift of the data which place the submittal flag of A in the third primary device column (as well as other shifts). This has no effect on the data performance, but it is noted as a potential cleanup issue.

EM

The EPA QA checker indicated that some emissions were outside the normal expected range. While this is a guideline and not a specific fault, this listing could be reviewed for specifically high values.

CH_4, EC, and OC were flagged as errors since these values are not in the EPA pollutant code table.

PE

There are a few records with the units M2 and MASS that were not in the EPA QA checker table. It could be determined if these values should be added, or whether there are appropriate substitutes.

There are a few remaining records with operating times outside the EPA QA Checker ranges.

<u>EP</u>

There are a few remaining records with operating parameters and seasonal sums outside the normal expected range.

The SCC 30202000 has not yet been added to the EPA QA Checker SCC database.

<u>ER</u>

A significant number of records are missing the supplementary coordinate reference information (Horizontal data measure, horizontal data accuracy, horizontal collection method code).

A number of records indicate coordinates outside of county boundaries – the reasons why this may occur were explained in the coordinate augmentation section earlier in this document.

A number of records also indicate stack parameters outside of ranges expected by the EPA QA checker. This is due either to the S/L/T agency specifically requesting not to change the values or to default values in the EPA table which fall outside of the EPA QA Checker ranges.

<u>EU</u>

SIC code 3041 is not in the SIC codes table.

<u>SI</u>

The modeled inventories (particularly the NH_3 and CAFO inventories) did not provide zip code information with the site data. This accounts for a tremendous number of the invalid zip code errors found when running the EPA QA checker. There are other records with zip code errors in addition to these; however, these inventories are the source of the majority of these errors.

NAICs codes are missing on some records.

<u>TR</u>

REPORT_CERTIFIER should be corrected to REPORT CERTIFIER.

Some records are missing the transaction creation date information.

C. Area Source Inventory Methods

1. Data Sources

For each S/L/T inventory submitted to EPA, Table 7 provides a summary of the number of counties and the pollutants included in each S/L/T inventory. For comparison purposes, the table shows the number of counties in each area source inventory included in the 2002 preliminary NEI and the number of counties in each state.

The states of IA and LA did not submit an area source inventory for the CAPs. For the state of NE, the data shown in Table 7 are from its area source inventory submittal to EPA. However, NE's area source inventory contained emissions for small point sources and NE subsequently moved the small point sources to the its point source inventory. IA, LA, NE, and OK requested that the 2002 preliminary NEI be used for their area source inventory for the CAPs except for categories (i.e., prescribed burning, agricultural burning, and agricultural dust) for which they requested that the CENRAP-sponsored inventory be used instead of the NEI. The NH_3 inventories that IA and LA submitted to EPA were maintained in the CENRAP inventory. In addition, Omaha did not submit an area source inventory; therefore, the 2002 preliminary NEI was used as the area source data for the CENRAP inventory for Omaha. OK's original inventory submittal to EPA was a copy of the 2002 preliminary NEI, but the emission values were rounded to two decimal places. OK's inventory was updated with the unrounded emission values in the 2002 preliminary NEI (February 2004 version).

The area source inventories obtained from EPA were loaded into Oracle in NIF 3.0 into one data set. Then, the following updates were performed on the consolidated data set, if necessary:

- HAP records were removed since the inventory will support regional haze, fine PM, and ozone modeling.

- Pollutant codes were corrected to make them NIF 3.0 compliant (e.g., update PMPRI pollutant code to PM-PRI). Additionally, other codes were identified for remediation on a case-by-case basis.

- Records with a submittal flag indicating deletions (submittal_flag = 'D' or 'RD') were removed from the inventories.

- Null values in the tribal code field were updated to '000' since this field is a part of the data key that defines records as unique in all five NIF tables.

Table 7. Summary of Pollutants and Number of Counties Included in Area Source Inventories

State/Local/Tribal Agency	CO	NH_3	NO_x	PM-PRI	PM10-PRI	PM25-PRI	PM10-FIL	PM25-FIL	PM-CON	SO_2	VOC	Number of Counties in 2002 S/L/T Inventory	Number of Counties in 2002 Preliminary NEI	Number of Counties in State
AR	x	x	x		x	x				x	x	75	75	75
IA		x										99	99	99
KS	x	x	x		x	x				x	x	105	105	105
LA		x										64	64	64
MN	x	x	x		x					x	x	87	87	87
Fond du Lac Band of the Minnesota Chippewa Tribe	x		x	x	x					x	x	NA[1]	NA	NA
MO	x	x	x		x	x				x	x	115	115	115
NE-State	x	x	x		x		x			x	x	79	93	93
NE-Lincoln (Lancaster County)	x	x	x		x	x				x	x	1	1	93
NE-Omaha (Douglas County)[2]												1	1	93
OK	x	x	x		x	x	x	x	x	x	x	77	77	77
TX	x	x	x		x	x	x	x	x	x	x	254	254	254

[1] NA = Not Applicable.

[2] Omaha's area source inventory is included in the state of NE's inventory submittal. Omaha did not submit its own area source inventory to EPA.

The following NIF plus fields were added to the EP, PE, EM, and CE tables:

- Data Source Codes:

For the area and nonroad inventory data, the data source codes were based on the following 9-character format:

[Data Origin]-[Year]-[Grown/Not Grown/Carried Forward]-[PM Augmentation Code]

Code	**Field Length**
Data Origin	1
Year	3 (including leading hyphen)
Grown/Not Grown/Carried Forward	2 (including leading hyphen)
PM Augmentation	3 (including leading hyphen)

Data Origin Codes

Code	**Description**
S	State agency-supplied data
L	Local agency-supplied data
R	Tribal agency-supplied data
P	Regional Planning Organization-generated data
E	EPA/Emission Factor and Inventory Group (EFIG)-generated data

Year Codes

Year for which data were supplied (e.g., Year = -02 for 2002), or from which prior year data were taken (e.g., Year = -99 for 1999; -01=2001).

Grown/Carried Forward/Not Grown Codes

Code	**Description**
-G	Used when emissions in a pre-2002 inventory were grown to represent 2002 emissions.
-F	Used when emissions in a pre-2002 inventory were carried forward and included in the 2002 inventory without adjustment for growth.
-X	Used when the emissions were not grown or were not carried forward. For example, X was used when emissions were calculated for the 2002 inventory using 2002 activity, or when data were replaced with 2002 S/L/T data.

PM Augmentation Codes

-PA	PM Augmented Emissions: Record for PM_{10}/$PM_{2.5}$ emissions that were updated or added using ad-hoc updates.

-PC PM Augmented Emissions: Record added for PM_{10}/$PM_{2.5}$ emissions estimated using the PM Calculator.

-PR PM Augmented Emissions: Record added for PM_{10}/$PM_{2.5}$ emissions estimated using ratios of PM_{10}-to-PM or $PM_{2.5}$-to-PM_{10}. If PM_{10} and $PM_{2.5}$ emissions were equal and one of the pollutants was assigned this code, the ratio was assumed to be 1.

2 QA Review

QA review was conducted on the S/L/T area source inventories in accordance with the QA procedures specified in the QAPP for this project (CENRAP, 2004b). The following discusses the QA checks that were completed during preparation of the consolidated data set.

a. County and SCC Coverage

The county coverage in the state inventories appeared to be reasonable for all states. The SCC coverage was difficult to evaluate simply by showing a count of the number of SCCs by state. Each S/L/T inventory was compared to the preliminary 2002 NEI, and area source categories in the NEI but not in a S/L/T inventory was sent to each agency for review. Each S/L/T agency then selected the NEI categories that were then added to the CENRAP inventory.

b. Pollutant Coverage

The pollutant coverage in the S/L/T inventories was complete for all pollutants except for PM_{10} and $PM_{2.5}$. Diagnosis and resolution of PM_{10} and $PM_{2.5}$ pollutant emissions is discussed later in section II.C.4.

c. EPA QA Summaries Sent to S/L/T Agencies

Under a separate project with EPA, Pechan performed QA review of the S/L/T area source inventories. This QA review involved running EPA's QA program on each data set to identify and resolve QA issues. Using the results of this QA work, Pechan prepared two sets of QA summaries that EPA sent to the S/L/T agencies. Pechan contacted each S/L/T agency with QA issues. The following explains these two summaries:

<u>High-level Summary of S/L/T Inventories Submitted to EPA</u>:

The first summary was an Excel workbook file with four spreadsheets that provided the following information:

- 2002 Nonpoint File Names: This spreadsheet documented names and formats of the files that EPA received from the S/L/T agencies and the dates on which they were transferred to Pechan.

- 2002 Nonpoint Summary: This spreadsheet documented the jurisdiction of the submitting agency (i.e., S/L/T agency), type of inventory (i.e., criteria, HAP, or

both), a comparison of the number of the counties in the inventory to the total number of counties in the state to identify the geographic coverage of the inventory, a unique list of CAP codes, and the total number of area source SCCs. This spreadsheet also indicated if any nonroad or onroad emissions data were moved from the agency's area source inventory to its nonroad or onroad inventory).

- 2002 Nonpoint Emission Sums: This spreadsheet summarized emissions by start date, end date, and emission type and assigned the appropriate code to the emission type period NIF plus field.

- 2002 Nonpoint Error Summary: This spreadsheet provided a copy of the "SummaryStats" table from the EPA QA program (EPA, 2004a). This table provided the count of records for each NIF 3.0 table and identified the number of records with errors by type of error.

Detailed Summary of QA Issues:

This summary (sent to S/L/T agencies on August 11) was prepared in a text file that listed by state and NIF table the number of records with errors, and provided corrections for the errors. To support documentation of corrections to some of the errors in the text file, Pechan prepared an Excel workbook file that summarized the following errors and corrections by state: invalid pollutants codes; invalid units; invalid maximum achievable control technology (MACT) codes; and invalid and inactive SCCs. A spreadsheet was also included to show the mapping of Standard Industrial Classification (SIC) codes to North American Industrial Classification System (NAICS) codes. This crosswalk was used to correct invalid NAICS codes if a valid SIC code was available in the S/L/T inventories and vice versa.

d. Additional QA for the CENRAP Area Source Inventory

The following explains additional QA and data tracking that was performed for the CENRAP inventory. The following data elements were reviewed to identify QA issues:

- Range Errors;
- PM Emissions Consistency and Completeness;
- Control Device Codes and Control Efficiency Values;
- Start and End Dates;
- Annual and Daily Emissions Comparison; and
- Comparison of S/L/T Inventories to the 2002 Preliminary NEI.

For each S/L/T inventory for which QA issues were identified, a separate QA Summary Report was prepared in an Excel Workbook file, and sent to each S/L/T agency for review. The S/L/T agencies provided directions in the Excel Workbook file, via e-mail, or by submitting revised records in NIF 3.0 in an Access database to correct the inventories. The QA reports are discussed under section II.C.3.

Range Errors

The EPA's QA program contains routines that compare annual emission values, numeric fields in the PE and EP tables, and other temporal numeric fields against a range of values. The QA program flags records that are less than or greater than the range of values for review. Pechan summarized the range errors for the S/L/T agencies to review and provide corrections. According to EPA, the ranges to which values in inventories are compared represent "normal" ranges that are based on percentiles from previous inventories. The range values are conservative in that EPA wants to identify suspicious values even though the values may be real (Thompson, 2002).

PM Emissions Consistency and Completeness Review

The following consistency checks were performed at the EM table data key level (for annual emissions) to compare PM emissions:

- If an SCC was associated with a PM emission record, but was missing one or more of the following (as appropriate for the SCC [i.e., PM-CON is associated with fuel combustion only]): PM10-FIL, PM10-PRI, PM25-FIL, PM25-PRI, or PM-CON, the record was flagged for review.

- The following equations were used to determine consistency:

  PM10-FIL + PM-CON = PM10-PRI
  PM25-FIL + PM-CON = PM25-PRI

- The following comparisons were made to determine consistency:

  PM10-PRI >= PM10-FIL
  PM25-PRI >= PM25-FIL
  PM10-PRI >= PM-CON
  PM25-PRI >= PM-CON
  PM10-FIL >= PM25-FIL
  PM10-PRI >= PM25-PRI

If the data failed one of these checks it was diagnosed as an error. If a S/L/T agency did not provide corrections to these errors, the errors were corrected/filled in according to an augmentation procedure explained in section II.C.4.

For information purposes, all PM-PRI and PM-FIL records were flagged to indicate that these pollutants were included instead of, or in addition to, the standard PM_{10}, $PM_{2.5}$, and PM-CON pollutants.

Control Device Type and Control Efficiency Data Review

The control equipment codes in the “Primary Device Type Code” and “Secondary Device Type Code” fields were reviewed to identify invalid codes (i.e., codes that did not exist in the NIF 3.0 reference table) and missing codes (e.g., records with a null or uncontrolled code of 000 but with control efficiency data).

QA review of control efficiency data involved diagnosis of two types of errors. First, records were reviewed to identify control efficiency values that were reported as a decimal rather than as a percent value. Records with control efficiencies with decimal values were flagged as a potential error (although not necessarily an error, since the real control efficiency may be less than 1 percent). Records with a 1% control efficiency value were also identified for review by the S/L/T agency to determine if the value was reported as a decimal in its internal data system but rounded to 1% when the data were converted to NIF 3.0.

The second check identified records where 100% control was reported in the CE table, but the emissions in the EM table were greater than zero and the rule effectiveness value in the EM table was null, zero, or 100% (implying 100 percent control of emissions). Because many agencies did not populate the rule effectiveness field or a default value of zero was assigned, records with null or zero rule effectiveness values were included where the CE was 100% and emissions were greater than zero. For records that met these criteria, Pechan consulted with the S/L/T agency to determine if corrections were needed to any of the fields.

Start and End Date Checks

QA review was conducted to identify start and end date values in the PE and EM tables to confirm consistency with the inventory year in the transmittal table, and to confirm that the end date reported was greater than the start date reported.

Annual and Daily Emissions Comparison

The S/L/T inventories were reviewed to determine if any of the following conditions existed:

- Multiple records coded at the SCC level as emission type 30, but with different start and end dates. While not a true duplicate, this may indicate an error or inclusion of both annual and seasonal values.

- Multiple records coded at the SCC level as a daily emission type (27, 29, etc.) but with different start and end dates. While not a true duplicate, this may indicate an error or just inclusion of additional types of daily emissions.

- Multiple records coded at the SCC level with the same start and end date, but different emission types. While not a true duplicate, this may indicate an error or just inclusion of additional types of daily emissions.

- Any “DAILY” type record that was missing its associated “ANNUAL” record was flagged for review.

- Any “DAILY” type record that was greater than its associated “ANNUAL” record was flagged for review.

3. Responses from State, Local, and Tribal (S/L/T) Agencies

QA Summary Reports were sent to the S/L/T agencies to review the QA issues identified. The S/L/T agencies were asked to return these reports to CENRAP with their corrections documented in the reports. These reports were then used to document revisions to the S/L/T inventories. The QA Summary Reports containing the revisions provided by the S/L/T agencies are provided in Excel Workbook files with this report. The names of the files are provided in Table 8. Note that a QA Summary Report was not prepared for NE and OK since the area source inventory for these two states is a copy of the 2002 NEI. OK provided an inventory for SCC 2310000000 (Industrial Processes / Oil and Gas Production: SIC 13 / All Processes / Total: All Processes) for VOC, NO_x, and CO that was incorporated into the CENRAP inventory.

Table 8. QA Summary Reports for S/L/T Area Source Inventories

S/L/T Agency	Excel Workbook File Name of QA Summary Report
AR	AR_NP_QA_Report_092404.xls
Fond du Lac Band of the Minnesota Chippewa Tribe	Fonddulac_NP_QA_Report_083004.xls
IA	IA_NP_QA_Report_090204.xls
KS	KS_NP_QA_Report_090104.xls
LA	LA_NP_QA_Report_090304.xls
MN	MN_NP_QA_Report_092304.xls
MO	MO_NP_QA_Report_091704.xls
NE - Lancaster County (Lincoln)	NE_Lancaster_NP_QA_Report_082704-approved.xls
TX	TX_NP_QA_Report_090904_v3.xls

The first spreadsheet in each QA Summary Report defines the remaining spreadsheets in the Excel Workbook file and provides instructions for communicating revisions. Table 9 provides a list of the QA summaries (note that a spreadsheet was not included in an agencies report if there were no QA issues).

Table 9. Summary of Spreadsheets Provided in QA Summary Reports for Area Source Inventories

Name of Spreadsheet	Content/Instructions
Summary Stats	This spreadsheet is a copy of the “SummaryStats” table generated by the EPA’s QA program. This shows the results of running the QA program on the August 6 version of the area source inventory files EPA provided to the S/L/T agencies after correcting referential integrity and duplicate record issues.
Lookup Errors	This spreadsheet provides a unique list of NIF 3.0 reference table “Lookup Errors” identified by the EPA’s QA program. The S/L/T agency should provide corrections to the lookup errors or indicate in the “Approved” column in this spreadsheet if it accepts the correction provided in the “Correction” Column.
Range Errors	This spreadsheet details the range errors identified by the EPA’s QA program.
Emission Type Period	This spreadsheet identifies EM table records as containing annual, seasonal, or daily emissions in the NIF plus field named “Emission Type Period.” This NIF plus field, once populated, will be used to prepare emissions summaries on a consistent temporal basis.
PMx Issues1	This spreadsheet documents the results of QA review conducted on PM10 and PM2.5 emissions as required by the Quality Assurance Project Plan (QAPP) and Draft Methods Document for this project.
PMx Issues2	This spreadsheet provides additional details regarding PM10 and PM2.5 QA issues referred to in the “PMx Issues1” spreadsheet.
NEI Categories not in State EI	The spreadsheet provides a unique list of the SCCs in the preliminary 2002 NEI that did not appear in the agency’s inventory submittal to EPA. The spreadsheet shows the number of counties in which the SCC appears in the NEI, and provides the NEI annual emissions in tons. See the “State to NEI Comparison” spreadsheet for detailed comparison at state level to help identify the NEI categories to add or exclude from your inventory in this “NEI Categories not in State EI” spreadsheet. This spreadsheet does not include: 1. SCCs in the NEI that electronically match on the state and county FIPS and SCC in the agency’s inventory; and 2. SCCs in the NEI that are different than the agency’s SCC but for the same category. For example, if an agency uses a general SCC for a category and the NEI uses SCCs that provide more detail, the SCCs in the NEI are not included in this spreadsheet. The agency should review the spreadsheet to make sure that all double counting of emissions between the agency’s inventory and the NEI has been eliminated.
State to NEI Comparison (provides additional data to supplement the data in the “NEI Categories not in State EI” spreadsheet)	This spreadsheet compares the SCCs in the S/L/T inventory to the SCCs in the 2002 preliminary NEI at the state-level. The number of counties that appear for each SCC in your state is also provided. This spreadsheet should be used to help make decisions on the NEI categories you want added and excluded from the list provided in the “NEI Categories not in State EI” spreadsheet.

4. Gap Filling and Augmentation

The following discusses the augmentation procedures that were applied to the S/L/T inventories to improve the inventories or to fill in missing data not supplied by the S/L/T agencies.

a. CENRAP-Sponsored Inventories

CENRAP sponsored inventory development for source categories of NH_3 and planned burning (i.e., prescribed burning, rangeland burning, and agricultural field burning) and agricultural dust area source categories. For each of these categories, each S/L/T agency was requested to complete a table to indicate if it (1) included the CENRAP-sponsored inventory in the inventory it submitted to EPA; (2) included its own estimates for a category in the inventory it submitted to EPA; or (3) if it did not include a category in its inventory, if the CENRAP-sponsored inventory or the 2002 preliminary NEI should be used as the source of data for the category. The results of this request are summarized in Table 10.

Table 10. Summary of CENRAP-Sponsored Inventories Included in the Area Source Consolidated Emissions Inventory

Area Source Category	SCCs	CENRAP Inventory Included in S/LT Inventory Submitted to EPA	S/L/T Inventory Used Instead of CENRAP Inventory			CENRAP Inventory Added to S/L/T Inventory	Preliminary NEI Used Instead of CENRAP Inventory
		Monthly	**Annual**	**Summer Day**	**Winter Day**	**Annual**	**Annual**
Planned Burning Inventories (pollutants included in S/L/T inventories are listed at the bottom of this table)[1]							
Prescribed Burning for Forest Management	2810015000		AR; TX; Lancaster County, NE; Tribal	AR, TX	AR, TX	IA, KS, LA, MN, MO, NE (state), OK	
Prescribed Burning of Rangeland	2810020000		TX; Lancaster County, NE	TX		IA, KS, LA, MN, MO, NE (state), OK	
Agricultural Field Burning	28015001xx; 28015002xx		AR; TX; Lancaster County, NE	TX		IA, KS, LA, MN, MO, NE (state), OK	
Fugitive Dust Inventories For PM10-PRI and PM25-PRI							
Agricultural Crop Tilling, Harvesting, and Other Activities	2801000003		AR	AR	AR	IA, KS, LA, MN, MO, NE (state), OK, TX	
NH_3 Inventories[2]							
Animal Husbandry (Livestock)	28050xxxxx	IA, KS, LA, MO	AR, TX	TX	TX	MN; NE (state); Lancaster County, NE; OK	
Agriculture Fertilizer Application	28017000xx	IA, KS, LA, MO	AR, TX			MN; NE (state); Lancaster County, NE; OK	
Food and Kindred Products - Refrigeration	2302080002	IA, KS, LA, MO	AR			MN, NE (state), OK

Public Owned Treatment Works	2630020000	KS, MO	TX	TX		MN; NE (state); Lancaster County, NE; OK	IA, LA
Other Combustion - Forest Wildfires	2810001000	MO	KS, TX	KS, TX		MN	IA; LA; NE (state); Lancaster County, NE; OK

Table 10 (continued)

Area Source Category	SCCs	CENRAP Inventory Included in S/LT Inventory Submitted to EPA	S/L/T Inventory Used Instead of CENRAP Inventory			CENRAP Inventory Added to S/L/T Inventory	Preliminary NEI Used Instead of CENRAP Inventory
		Monthly	Annual	Summer Day	Winter Day	Annual	Annual
Other Combustion - Human Perspiration and Respiration	2810010000	IA, KS, LA, MO	AR, TX	AR, TX	AR	MN; NE (state); Lancaster County, NE; OK	
Domestic Animals Waste	280601xxxx	IA, KS, LA, MO	TX	TX		MN; NE (state); Lancaster County, NE; OK	
Wild Animals Waste	28070xxxxx	IA, KS, LA, MO	TX	TX		MN; NE (state); Lancaster County, NE; OK	
Natural Sources/Biogenic (Vegetation/Forests /Land Use)	2701xxxxxx	IA, KS, LA	TX	TX		NE (state), OK	
Light Duty Gasoline Vehicles	2201001000	IA, KS, LA					
Light Duty Diesel Vehicles	2230001000	IA, KS, LA					

[1] The following identifies the pollutants included in the planned burning inventories by S/L/T agency:

Prescribed Burning for Forest Management
AR: CO, NO_x, VOC, PM10-PRI, PM25-PRI
Fond du Lac Band of the MN Chippewa Tribe: CO, PM-PRI, PM10-PRI, PM25-PRI
IA, KS, LA, MN, MO, OK; NE (state); Lancaster County, NE: CO, NO_x, NH_3, SO_2, VOC, PM10-PRI, PM25-PRI
TX: CO, NO_x, NH_3, SO_2, VOC, PM10-PRI, PM10-FIL, PM25-PRI, PM25-FIL

Prescribed Burning of Rangeland
IA: CO, NO_x, SO_2, VOC, PM10-PRI, PM25-PRI
KS; LA; MN; MO; OK; NE (state); Lancaster County, NE: CO, NO_x, NH_3, SO_2, VOC, PM10-PRI, PM25-PRI
Lancaster County, NE: CO, NO_x, PM10-PRI, PM25-PRI
TX: CO, NO_x, NH_3, VOC, PM10-PRI, PM10-FIL, PM25-PRI, PM25-FIL

Agricultural Field Burning
AR: CO, VOC, PM10-PRI, PM25-PRI
IA, KS, LA, MN, MO, OK; NE (state); Lancaster County, NE: CO, NO_x, NH_3, SO_2, VOC, PM10-PRI, PM25-PRI
TX: CO, NO_x, NH_3, VOC, PM10-PRI, PM10-FIL, PM25-PRI, PM25-FIL

[2] The CENRAP-sponsored NH_3 inventories were prepared for monthly emissions. The monthly emissions were summed to calculate annual emissions. The annual emission records were added to the area source inventory to support preparation of emission summaries.

b. PM Augmentation

Procedures were developed to estimate missing pollutant data from data provided by the S/L/T agencies in order to develop a complete set of PM10-PRI and PM25-PRI emissions to support air quality modeling. The following discusses the procedures for fossil fuel combustion and residential wood combustion sources first followed by the procedures for all other area sources of PM emissions.

Fossil Fuel Combustion Sources

Fossil fuel combustion sources include industrial, commercial/institutional, and residential anthracite coal, bituminous/subbituminous coal, distillate oil and kerosene, residual oil, natural gas, and liquefied petroleum gas (LPG). All of these sources emit both filterable and condensible emissions. The QA review of the PM emissions data for these sources focused on verifying that the emissions reported in the S/L/T inventories included both filterable and condensible emissions. The emissions for these pollutants can be reported individually (i.e., as filterable and condensible separately) or as primary emissions (i.e., the sum of the filterable and condensible emissions). The QA review also focused on evaluating the emission factors reported in the S/L/T inventories to determine if they were reasonable.

To support the QA review effort, the uncontrolled PM emission factors shown in Table 11 were compiled from AP-42. The emission factors reported in the S/L/T inventories were compared to the emission factors in this table. Emission factors that appeared too high or too low were flagged for review by the S/L/T agency. In addition, inventory data were flagged for review by the S/L/T agency if the emissions were reported under the primary PM pollutant codes but the emission factors matched with the emission factors for filterable PM in Table 11. Finally, if emission factors were not reported in the S/L/T agency inventory, the emission factors were back-calculated using the throughput data (if available), emissions, rule effectiveness values, and control efficiency data (if available). The back-calculated emission factors were compared to the factors in Table 11 to identify data with major difference between the factors. It is emphasized that the uncontrolled emission factors in Table 11 were used as a reference for reviewing S/L/T inventory data. The emission factors in this table should not be construed to be the best available for all S/L/T agencies since the emission factors will vary depending on the composition of the boiler population in an agency’s area source inventory.

The states of IA, KS, LA, NE, and OK used the fossil fuel combustion inventory in the preliminary 2002 NEI for the CENRAP inventory. Revisions to the NEI for residential LPG and kerosene were completed after the preliminary 2002 NEI was released in February 2004; the revised inventories for these two categories were included in the CENRAP inventory for IA, KS, LA, NE, and OK.

AR, MN, and TX provided their own inventory for all fossil fuel combustion categories. AR’s inventory reported filterable emissions under the primary pollutant code, but AR corrected its inventory and provided updates to the CENRAP inventory.

Table 11. Area Source Industrial, Commercial/Institutional, and Residential Fossil Fuel Combustion Uncontrolled Emission Factors for PM10-PRI/FIL, PM25-PRI/FIL, and PM-CON

Pollutant[1]	Uncontrolled Emission Factor (EF)	EF Numerator	EF Denominator	Calculated Uncontrolled EF	Reference

[1] PM10-PRI EF = sum of PM10-FIL and PM-CON EFs; PM25-PRI EF = sum of PM25-FIL and PM-CON EFs.

MO used the NEI data for industrial residual oil combustion, commercial/institutional residual oil combustion, and residential anthracite coal combustion. MO's inventory contained several PM QA issues, and MO provided corrections (using AP-42 emission factors) that were incorporated into the CENRAP inventory. MO did not provide any PM_{10} or $PM_{2.5}$ emissions data for forest wildfires (SCC 2810001000).

MN provided corrections to PM QA issues that were incorporated into the CENRAP inventory. Lancaster County, NE provided its own inventory for residential natural gas fired furnaces, and requested that no other industrial, commercial/institutional, or residential fossil fuel combustion categories in the NEI be added to its inventory. The tribal inventory did not contain any fossil fuel combustion inventory data.

TX's inventory was revised to address the PMx QA issues listed in the QA Summary Report (TX_NP_QA_Report_090904_v3.xls). Most of the QA issues in TX's inventory were associated with the sum of the filterable and condensible emissions not equaling the primary emissions. This issue was corrected by replacing the primary emissions with the sum of the filterable and condensible emissions. Many of the QA issues were associated with daily emissions. Since daily emissions are not needed to support regional haze air quality modeling, TX and CENRAP agreed to remove the daily PMx emissions from TX's inventory.

Residential Wood Combustion

The states of IA, LA, NE, and OK (including Lancaster County) used the residential wood combustion inventory in the preliminary 2002 NEI for the CENRAP inventory. Revisions to the NEI for residential wood combustion were completed after the preliminary 2002 NEI was released in February 2004; the revised inventories for this category was were included in the CENRAP inventory for IA, LA, NE, and OK.

The states of AR, KS, MN, MO, and TX prepared their own residential wood combustion inventories. KS and MO provided replacement inventories that disaggregated the emissions in more detail (i.e., by separate SCCs for fireplaces and woodstoves) than provided in their original inventory submittal to EPA. In addition, KS, MO, and MN revised the emission factors and provided updated emissions for CO and PM10-PRI and PM25-PRI that originate from the NEI method for this category to address a unit conversion issue identified with the NEI emission factors.

Other Sources of PM Emissions

For states that provided only PM10-FIL and PM25-FIL emissions, PM10-PRI emissions were set equal to PM10-FIL emissions and PM25-PRI emissions were set equal to PM25-FIL emissions. The PM10-PRI and PM25-PRI emissions that were added to the inventory were assigned a data source code of S-02-X-PR where S-02-X code represents the code assigned to the PM10-FIL and PM25-FIL emissions provided by the S/L/T agency and the "-PR" indicates that the ratio was applied to estimate the primary emissions (in this case, the ratio of primary to filterable emissions is "1").

PM25-PRI emissions missing from S/L/T inventories were estimated by applying a ratio of PM25-PRI to PM10-PRI emissions to the PM10-PRI emissions provided by the S/L/T agency. Table 12 identifies the agencies with SCCs for which ratios were applied to estimate PM25-PRI emissions. This table also shows the ratios and the reference for the ratios.

TX's inventory for agricultural tilling (SCC 2801000000) contained records where the filterable emissions exceeded the primary emissions. These emissions were grown from Version 3 of the 1999 NEI. This issue was corrected by setting the PM10-PRI and PM25-PRI emissions equal to the PM10-FIL and PM25-FIL emissions.

Table 12. SCCs for which PM25-PRI Emissions were Estimated by Applying a Ratio to the PM10-PRI Emissions in the S/L/T inventory

SCC	SCC Description	Agency	Ratio of PM25-PRI to PM10-PRI	Reference
2294000000	Mobile Sources : Paved Roads : All Paved Roads : Total: Fugitives	Fond du Lac Band of the Minnesota Chippewa Tribe	0.25	NEI Method
2296000000	Mobile Sources : Unpaved Roads : All Unpaved Roads : Total: Fugitives	Fond du Lac Band of the Minnesota Chippewa Tribe	0.15	NEI Method
2505020000	Storage and Transport : Petroleum and Petroleum Product Transport : Marine Vessel : Total: All Products	MO	1	No data available; assumed PM25-PRI equals PM10-PRI
2535010000	Storage and Transport : Bulk Materials Transport : Rail Car : Total: All Products	Lancaster County, NE	1	No data available; assumed PM25-PRI equals PM10-PRI
2810015000	Miscellaneous Area Sources : Other Combustion : Prescribed Burning for Forest Management : Total	Fond du Lac Band of the Minnesota Chippewa Tribe	1	No data available; assumed PM25-PRI equals PM10-PRI
2810020000	Miscellaneous Area Sources : Other Combustion : Prescribed Burning of Rangeland : Total	KS, LA, and NE	0.8	Based on average ratio of PM25-PRI to PM10-PRI for emissions data provided by other CENRAP states

2810050000	Miscellaneous Area Sources : Other Combustion : Motor Vehicle Fires : Total	MO, TX	0.91	NEI Method

c. 2002 NEI

Merging of NEI Data into S/L Inventories

The area source inventory provided by each S/L agency was compared to the 2002 NEI to identify categories in the NEI that were not in each S/L inventory. The list of categories identified was provided to each S/L agency and each agency then selected the NEI categories to be added to their inventory. Identification of categories included in the 2002 NEI but not in a S/L inventory involved a two-step process. First, Pechan identified the categories in the NEI that did not have an electronic match on the data key of the EM table between the S/L inventory and the NEI. Then, Pechan manually compared the NEI categories without an electronic match to

the S/L inventory to identify and eliminate NEI categories that were in the S/L inventory but had a different SCC. For example, a state inventory may use a general SCC for a category while the NEI may use different SCCs to breakout emissions at a finer detail. Examples of categories where this typically occurred include residential wood combustion, open burning of land clearing debris, solvent utilization, and petroleum marketing and transportation categories. In addition, if a S/L agency requested that a CENRAP-sponsored inventory be added to its inventory, the NEI categories that overlapped with the CENRAP-sponsored categories were removed from the list of NEI categories considered for incorporation into a S/L inventory.

Note that the preliminary 2002 NEI did not contain any data for the Fond du Lac Band of the Minnesota Chippewa Tribe. Therefore, a comparison of the tribal inventory to the NEI was not made.

The source categories in the 2002 NEI that were added to a S/L/T inventory can be identified where the data source code starts with “E”. These categories can be identified using the data source code field in the NIF 3.0 files or in the summary of area source emissions that contains the data source code.

Revisions to the Preliminary 2002 NEI

During preparation of the CENRAP inventory, EPA completed revisions to the emissions for six categories in the preliminary 2002 NEI released in February 2004. As agreed to with each S/L agency, the revised emissions were used in the CENRAP inventory in lieu of the preliminary 2002 NEI emissions if the agency requested that the category be included.

1. Non-Residential Construction (SCC 2311020000): 2002 emissions data replaced data in preliminary 2002 NEI that were carried forward from 1999 NEI.

2. Highway Construction (SCC 2311030000): 2002 emissions data replaced data in preliminary 2002 NEI that were carried forward from 1999 NEI.

3. Open Burning of Land Clearing Debris (SCC 2610000500): 2002 emissions data replaced data in preliminary 2002 NEI that were carried forward from 1999 NEI. The activity for this category was based on activity prepared for the non-residential and highway construction categories. For 2002, emissions were set to zero for counties with a population that was 80% urban or more based on 2000 Census data. This was not done for the 1999 NEI. For the NEI method, it was assumed that highly urban counties do not allow this activity to take place. Note that 2002 emissions data were already included in the preliminary 2002 NEI for the open burning of residential municipal solid waste, open burning of yard waste, and the residential construction categories.

4. Residential LPG Combustion (SCC 2104007000): 2000 emissions data replaced data in the preliminary 2002 NEI that were carried forward from 1999 NEI.

5. Residential Kerosene Combustion (SCC 2104011000): 2000 emissions data replaced data in the preliminary 2002 NEI that were carried forward from 1999 NEI.

6. Residential Wood Combustion (SCCs starting with 2104008xxx; 4 SCCs for fireplaces and 3 SCCs for woodstoves): The preliminary 2002 NEI emissions were revised to:
   (a) correct the CO, PM10-PRI, and PM25-PRI emission factors for fireplaces without inserts (this change doubled the emission factors associated with correcting an error in converting the values from g/kg to lb/ton);
   (b) correct the climate zone map for allocating national activity to states;
   (c) replace 1997 total residential wood consumption with 2001 estimates (this change reduced wood consumption for fireplaces with inserts and woodstoves);
   (d) update urban/rural population data to reflect 2002 estimates based on year 2002 total county population and year 2000 county ratios of urban/rural population to total population; and
   (e) change the data source code from E-02-X (this was incorrect) to E-01-X to reflect 2001 activity data adjusted to 2002.

5. Revisions to Address Comments

The following items were revised per state instruction during S/L/T agency review of the draft area source inventory:

a. Missouri

Missouri provided revisions to annual VOC emissions for the following surface coating categories to correct for double-counting of emissions in the draft inventory.

SCC	SCC Description
2401015000	Solvent Utilization : Surface Coating : Factory Finished Wood: SIC 2426 thru 242 : Total: All Solvent Types
2401020000	Solvent Utilization : Surface Coating : Wood Furniture: SIC 25 : Total: All Solvent Types
2401040000	Solvent Utilization : Surface Coating : Metal Cans: SIC 341 : Total: All Solvent Types
2401050000	Solvent Utilization : Surface Coating : Miscellaneous Finished Metals: SIC 34 - (341 + 3498) : Total: All Solvent Types
2401055000	Solvent Utilization : Surface Coating : Machinery and Equipment: SIC 35 : Total: All Solvent Types
2401060000	Solvent Utilization : Surface Coating : Large Appliances: SIC 363 : Total: All Solvent Types
2401065000	Solvent Utilization : Surface Coating : Electronic and Other Electrical: SIC 36 - 363 : Total: All Solvent Types
2401070000	Solvent Utilization : Surface Coating : Motor Vehicles: SIC 371 : Total: All Solvent Types

2401080000	Solvent Utilization : Surface Coating : Marine: SIC 373 : Total: All Solvent Types

For these SCCs, MO did not provide any daily emissions. The daily emissions in the draft inventory originated from the 1999 NEI. The daily emissions for some of the SCCs were greater than the annual emissions after incorporating the revised inventory supplied by MO. After discussing this issue with Missouri, the following revisions were made to the daily emissions:

(1) For records where Missouri's revised annual emissions were zero, the daily emissions were set to zero and the data source code was set to S-02-X; and

(2) For records where Missouri's revised annual emissions were greater than zero, the daily emissions were removed from the CENRAP inventory.

b. Minnesota

Minnesota provided a new inventory of annual VOC emissions for asphalt paving (SCC 2461021000) that was added to the final inventory. Minnesota provided revisions to annual CO, NH_3, NOX, PM10-PRI, PM25-PRI, SO_2, and VOC for the following commercial/institutional fossil fuel and wood combustion categories:

SCC	SCC Description
2103002000	Stationary Source Fuel Combustion : Commercial/Institutional : Bituminous/Subbituminous Coal : Total: All Boiler Types
2103004000	Stationary Source Fuel Combustion : Commercial/Institutional : Distillate Oil : Total: Boilers and IC Engines
2103005000	Stationary Source Fuel Combustion : Commercial/Institutional : Residual Oil : Total: All Boiler Types
2103006000	Stationary Source Fuel Combustion : Commercial/Institutional : Natural Gas : Total: Boilers and IC Engines
2103007000	Stationary Source Fuel Combustion : Commercial/Institutional : Liquified Petroleum Gas (LPG) : Total: All Combustor Types
2103008000	Stationary Source Fuel Combustion : Commercial/Institutional : Wood : Total: All Boiler Types
2103011000	Stationary Source Fuel Combustion : Commercial/Institutional : Kerosene : Total: All Combustor Types

c. Oklahoma

Daily VOC emissions for oil and gas exploration were removed. Oklahoma's area source inventory was taken from the preliminary 2002 NEI except that Oklahoma provided an inventory of annual VOC, NOX, and CO emissions for natural gas exploration that replaced the annual emissions from the preliminary NEI (that originated from Version 3 of the 1999 NEI). Oklahoma did not provide revisions to the old daily emissions. Given that the old daily emissions were not calculated from the new annual emissions supplied by Oklahoma, the daily emissions were removed from the CENRAP inventory.

d. Texas

Replaced emissions with more recent emissions estimates from the 2002 NEI for the following categories:

SCC	SCC Description
Residential Stationary Source Fuel Combustion	
2104002000	Bituminous/Subbituminous Coal / Total: All Combustor Types
2104004000	Distillate Oil / Total: All Combustor Types
2104006000	Natural Gas / Total: All Combustor Types
2104007000	Liquified Petroleum Gas (LPG) / Total: All Combustor Types
2104008001	Wood / Fireplaces: General
2104008002	Fireplaces: Insert; non-EPA certified
2104008003	Fireplaces: Insert; EPA certified; non-catalytic
2104008004	Fireplaces: Insert; EPA certified; catalytic
2104008010	Woodstoves: General
2104008030	Catalytic Woodstoves: General
2104008050	Non-catalytic Woodstoves: EPA certified
2104011000	Kerosene Combustion
Fugitive Dust from Roads	
2294000000	All Paved Roads / Total: Fugitives
2296000000	All Unpaved Roads / Total: Fugitives
Fugitive Dust from Construction	
2311010000	Residential / Total
2311020000	Industrial/Commercial/Institutional / Total
2311030000	Highway Construction
Storage and Transport / Petroleum and Petroleum Product Storage	
2501000000	All Storage Types: Breathing Loss / Total: All Products
2501080050	Airports : Aviation Gasoline / Stage 1: Total
2501080100	Airports : Aviation Gasoline / Stage 2: Total
Open Burning	
2610000100	Yard Waste - Leaf Species Unspecified
2610000400	Yard Waste - Brush Species Unspecified
2610000500	Land Clearing Debris
2610030000	Residential / Household Waste
Miscellaneous Area Sources / Agriculture Production - Crops	
2801000000	Cotton Ginning

e. Agricultural Tilling

The CENRAP-sponsored inventory for fugitive dust emissions from agricultural tilling (SCC 2801000003 - Miscellaneous Area Sources : Agriculture Production - Crops : Agriculture - Crops : Tilling) was updated on October 27, 2004. However, the timing of the revision was too late to incorporate into the December 8, 2004 draft CENRAP inventory. Therefore, the agricultural tilling emissions were updated to match those in the revised CENRAP-sponsored inventory for the states that elected to use the CENRAP-sponsored inventory.

f. Open Burning Categories

For the following open burning emissions categories that originate from the 2002 NEI (Data Source Code = E-02-X), removed CE records where the primary device type for miscellaneous controls (code 099) were associated with uncontrolled emissions in the emission table.

SCC	SCC Description
2610000100	Yard Waste - Leaf Species Unspecified
2610000400	Yard Waste - Brush Species Unspecified
2610000500	Land Clearing Debris
2610030000	Residential / Household Waste

6. QA Review of Final Inventory

Final QA checks were run on the revised data set to ensure that all corrections provided by the S/L/T agencies were incorporated into the S/L/T inventories and that there were no remaining QA issues that could be addressed during the duration of the project. After exporting the inventory in Oracle to an Access database in NIF 3.0, the EPA's QA program was run on the Access database and the QA output was reviewed to verify that all QA issues that could be addressed were resolved (EPA, 2004a).

One remaining issue that was not addressed concerns double counting of NH_3 emissions in the onroad inventory. The area miscellaneous source inventory for Iowa, Kansas, and Louisiana include NH_3 emissions for the following two SCCs that originate from the CENRAP-sponsored NH_3 inventory:

SCC	SCC Description
2201001000	Mobile Sources / Highway Vehicles - Gasoline / Light Duty Gasoline Vehicles (LDGV) / Total: All Road Types)
2230001000	Mobile Sources / Highway Vehicles - Diesel / Light Duty Diesel Vehicles (LDDV) / Total: All Road Types)

The onroad inventory includes NH_3 emissions for these source categories as well. Thus, if the area source inventory is revised in the future, these two SCCs should be removed from the area source inventory. For all three states and the two SCCs combined, the NH_3 emissions total to 8,735 annual tons. In each of the three states, the light-duty gasoline vehicles category accounts for 24 to 31 percent of the total area miscellaneous inventory for the state, but only 1 to 4 percent

when compared to total NH_3 emissions in the area and area miscellaneous inventories combined. At the CENRAP-region level, the percentages are less than 1 percent of total NH_3 emissions from all sources.

The output file from the EPA's QA program run on the area source inventory and the area miscellaneous source inventory is provided in an Access 2000 database along with the Access database containing the area and area miscellaneous inventory in NIF 3.0. The following lists the remaining QA issues that were not addressed during the duration of this project:

Area Source Inventory

Range Errors: There are 1,418 records in the EM table with emissions that exceed the maximum emissions in the QA program for the specified pollutant.

Lookup Errors: There are 333 records in the PE table and 6,548 records in the EM table with lookup errors. The look-up errors in both the PE and EM tables are associated with units that are not in the NIF 3.0 reference table, but EPA has indicated that the units will be added to the NIF 3.0 reference table.

Area Miscellaneous Source Inventory

Lookup Errors: There are 216,372 records in the PE table and 199,728 records in the EM table with lookup errors. The look-up errors in both the PE and EM tables are associated with units that are not in the NIF 3.0 reference table, but EPA has indicated that the units will be added to the NIF 3.0 reference table.

D. Nonroad Source Inventory Methods

Initially, work on the nonroad inventory was to be limited to the non-NONROAD Model categories for commercial and military aircraft, commercial marine vessel, and railroad locomotives. The CENRAP-sponsored inventory for the NONROAD Model categories was to be used to support air quality modeling and planning. However, during the project TX updated its inventory for the NONROAD Model categories and requested that this inventory be used instead of the CENRAP-sponsored inventory for the NONROAD Model categories. Since Pechan obtained the CENRAP-sponsored inventory for the NONROAD Model categories to support the preparation of emissions summaries, the CENRAP-sponsored inventory for the NONROAD Model categories in TX was replaced with TX's NONROAD Model inventory. Then, the inventories for aircraft, commercial marine vessel, and railroad locomotives were added to the NONROAD Model inventory for all S/L agencies to create a consolidated nonroad inventory for CENRAP.

The following discusses the QA that was completed on the inventories for aircraft, commercial marine vessel, and railroad locomotives and explains the data sources used to compile the inventories for these non-NONRAOD Model categories. QA review of the NONROAD Model inventory was completed under a separate CENRAP-sponsored project.

1. Data Sources

For each S/L/T inventory submitted to EPA, Table 13 provides a summary of the pollutants included in each inventory, and the number of counties for which data were provided for the aircraft, commercial marine vessel, and railroad locomotive categories. The table also shows the number of counties in the 2002 preliminary NEI for the aircraft, commercial marine vessel, and railroad locomotive categories and the number of counties in each state.

AR and TX provided emissions data for all three of the non-NONROAD Model categories. For the railroad locomotive category, KS, LA, MN, and MO included NH_3 emissions based on Carnegie Mellon University (CMU) model estimates in their inventories. MN also included CAP emissions in the inventory it submitted to EPA.

- The nonroad source inventories obtained from EPA were loaded into Oracle in NIF 3.0 into one data set. Then, the following updates were performed on the consolidated data set, if necessary:

- HAP records were removed since the inventory will support regional haze, fine PM, and ozone modeling.

- Pollutant codes were corrected to make them NIF 3.0 compliant (e.g., update PMPRI pollutant code to PM-PRI). Additionally, other codes were identified for remediation on a case-by-case basis.

- Records with a submittal flag indicating deletions (submittal_flag = 'D' or 'RD') were removed from the inventory.

- Null values in the tribal code field were updated to '000' since this field is a part of the data key that defines records as unique in all eight NIF tables.
- Added and populated the NIF plus fields listed in the previous discussion for the area source inventory.

- The CENRAP-sponsored inventory did not contain S/L agency contact information in the TR table. In addition, the TR table for the data taken from the preliminary 2002 NEI contained the contact information for EPA. Therefore, the TR table was updated to include the contact information that S/L agencies provided in their area source inventories.

Table 13. Summary of Pollutants and Number of Counties Included in Nonroad Source Inventories

State/Local/Tribal Agency	Sector	CO	NH_3	NO_x	PM10-PRI	PM25-PRI	PM10-FIL	PM25-FIL	PM-CON	SO_2	VOC	Number of Counties in 2002 S/L/T Inventory	Number of Counties in 2002 Preliminary NEI	Number of Counties in State
AR	Commercial Marine Vessels (CMV)	x	x	x	x	x				x	x	27	25	75
	Railroad Locomotives	x	x	x	x	x				x	x	75	75	75
	Aircraft	x	x	x	x	x				x	x	68	41	75
KS	Railroad Locomotives		x									2	105	105
LA	Railroad Locomotives		x									3	64	64
MN	Railroad Locomotives	x	x	x	x					x	x	81	87	97
MO	Railroad Locomotives		x									2	115	115
TX	CMV	x		x	x	x	x	x		x	x	19	19	254
	Railroad Locomotives	x	x	x	x	x				x	x	254	254	254
	Aircraft	x		x	x	x	x			x	x	167	124	254

2. QA Review

QA review was conducted on the inventories in accordance with the QA procedures specified in the QAPP for this project (CENRAP, 2004b). The following discusses the QA checks that were completed during preparation of the consolidated data set.

a. County and SCC Coverage

For the agencies that submitted inventories to EPA, the county coverage in the inventories appeared to be reasonable. However, the NH_3 inventories for KS, LA, MN, and MO covered significantly fewer counties than what the preliminary 2002 NEI covered. The differences in the county coverage for NH_3 emissions were due to differences in the methods used to prepare the state NH_3 inventory and the NEI.

b. Pollutant Coverage

The pollutant coverage in the S/L/T inventories was complete for all pollutants except that MN did not include PM25-PRI emissions for railroad locomotives in its inventory, and TX did not provide NH_3 emissions for commercial marine vessels and aircraft in its inventory. MN provided PM25-PRI emissions to fill this data gap. TX did not provide any NH_3 emissions for commercial marine vessels or aircraft.

c. Additional QA for the CENRAP Area Source Inventory

The QA procedures discussed previously for the S/L/T area source inventories were applied to the S/L inventories for aircraft, commercial marine vessels, and railroad locomotives.

3. Responses from S/L/T Agencies

The nonroad source inventories were revised to incorporate updates from MN and to incorporate TX's NONROAD Model inventory. No other QA issues were identified in the state inventories for the non-NONROAD Model categories.

4. Gap Filling and Augmentation

Table 14 provides a summary of the sources of data used to prepare the consolidated inventory for aircraft, commercial marine vessels, and railroad locomotives. For commercial marine vessels and railroad locomotives, the CENRAP-sponsored inventory was used for all states except for AR, MN, and TX who provided their own inventories. Note that the CMU Model NH_3 emissions that KS, LA, and MO included in their inventory submittals to EPA for railroads were replaced with NH_3 emissions in the CENRAP-sponsored inventory.

Table 14. Summary of Data Sources Used to Prepare the Consolidated Nonroad Inventory for Aircraft, Commercial Marine Vessels, and Railroad Locomotives

State/Local Agency	Source of Inventory Data	Notes
Commercial and Military Aircraft (SCC 227500xxxx - 227507xxxx)		
AR	State	
IA	2002 NEI	
KS	State	State inventory is based on the 2002 NEI
LA	2002 NEI	
MN	State	Included in point source inventory
MO	2002 NEI	
NE - Lancaster County	2002 NEI	
NE - State	2002 NEI	
OK	2002 NEI	
TX	State	
Commercial Marine Vessels (SCC 228000xxxx)		
AR	State	
IA	CENRAP Inventory	
KS	CENRAP Inventory	
LA	CENRAP Inventory	
MN	State	
MO	CENRAP Inventory	
NE - Lancaster County	CENRAP Inventory	
NE - State	CENRAP Inventory	
OK	CENRAP Inventory	
TX	State	
Railroad Locomotives (SCC 2285002006 - 2285002010)		
AR	State	
IA	CENRAP Inventory	
KS	CENRAP Inventory	
LA	CENRAP Inventory	
MN	State	
MO	CENRAP Inventory	
NE - Lancaster County	CENRAP Inventory	
NE - State	CENRAP Inventory	
OK	CENRAP Inventory	
TX	State	

AR, KS, MN, and TX included aircraft emissions in the inventories they submitted to EPA. However, MN included aircraft emissions in its point source inventory that were included in the point source inventory for CENRAP. KS' inventory was based on the aircraft inventory included in the preliminary 2002 NEI. CENRAP did not sponsor development of an inventory for commercial and military aircraft. Therefore, the 2002 NEI was used as the source of aircraft inventory data for the states that did not provide an inventory for this source category. QA review of PM emissions did not find any missing data after updating MN's inventory for railroad locomotives. Therefore, no PM augmentation was performed on the nonroad inventories.

5. Revisions to Address Comments

The nonroad inventory was revised for Minnesota to remove double-counting of emissions for SCC 2265008005 (Mobile Sources / Off-highway Vehicle Gasoline, 4-Stroke / Airport Ground Support Equipment / Airport Ground Support Equipment). Minnesota included emissions for this SCC in its point source inventory. The nonroad inventory contained only annual emissions for this SCC, which came from the CENRAP-sponsored nonroad inventory. The annual emissions removed from the nonroad inventory are as follows:

Pollutant	Annual Emissions (tons/year)	Counties Affected (State and County FIPS code)
VOC	8.65	27007, 27037, 27041, 27053, 27091, 27109, 27123, 27137, 27145, 27163
NOX	7.6	27007, 27037, 27041, 27053, 27091, 27109, 27123, 27137, 27145, 27163
CO	212.7	27007, 27037, 27041, 27053, 27091, 27109, 27123, 27137, 27145, 27163
SO_2	0.04	27053
PM10-PRI	0.07	27053
PM25-PRI	0.06	27053
NH_3	0.01	27053

6. QA Review of Final Inventory

Final QA checks were run on the revised data set to ensure that all corrections provided by the S/L/T agencies were incorporated into the S/L/T inventories and that there were no remaining QA issues that could be addressed during the duration of the project. After exporting the inventory in Oracle to an Access database in NIF 3.0, the EPA's QA program was run on the Access database and the QA output was reviewed to verify that all QA issues that could be addressed were resolved. The QA output is provided in an Access 2000 database along with the Access database containing the inventory in NIF 3.0.

The following lists the remaining QA issues that were not addressed during the duration of this project:

Range Errors: There are 260 records in the EM table with emissions that exceed the maximum emissions in the QA program for the specified pollutant.

Lookup Errors: There are 105,667 records in the EM table with CO_2 emissions that caused this error. CO_2 is not included in the reference table for valid NIF 3.0 pollutant codes. At the request of CENRAP, CO_2 emissions were kept in the inventory.

E. 2002 CEM Data Methods and Results

1. Introduction

The 2002 CEM data for the entire CENRAP modeling domain were collected and converted to SMOKE and the RPO data exchange protocol formats. A crosswalk file was developed in order to process CEM data for all four quarters of 2002 into the formats required by CENRAP.

CEM data were also compiled for the CENRAP Region for the years 2000, 2001, and 2003. The data for these years were combined with the 2002 CEM data to develop three (3) sets of temporal profiles. The sets of profiles generated include seasonal profiles, daily profiles by season, and hourly profiles by season. National Weather Service temperature data that were readily available were analyzed. Recommendations were made on whether or not to generate temporal profiles based on these parameters. Additional recommendations were made on the best approaches for assigning temporal profiles to individual units.

2. Data Sources

The data source for the CEM data for the years 2000 through 2003 is the EPA's website, specifically the following websites were used for acquiring raw data and reports to QA the CEM data:

- http://www.epa.gov/airmarkets/emissions/raw/index.html (Clean Air Markets data)
- http://cfpub.epa.gov/gdm/index.cfm?fuseaction=prepackaged.select (Emissions data and reports)
- http://www.epa.gov/airmarkets/emissions/prelimarp/ (more emissions reports)

The CEM units in the raw data sets were mapped to the appropriate source(s) in the consolidated 2002 point source inventory. We worked together with Pechan and the CENRAP states by soliciting feedback on the CEM units that we were not able to initially match up with the 2002 inventory. The mapping entailed matching a CEM unit (Office of Regulatory Information Systems [ORIS] ID and unit ID) to the state and county FIPS, Plant, Stack, and Segment identifier. The data were formatted into hour-specific emissions that are readable by the SMOKE modeling system and also in the RPO data exchange format.

CEM data for year 2002 for areas outside of the CENRAP were obtained from RPOs and EPA when the data were available. CEM data for the Visibility Improvement State and Tribal Association of the Southeast (VISTAS) states were obtained from the VISTAS RPO via the Alpine Geophysics ftp site (ftp agftp.com). The data consisted of hour-specific CEM data for the year 2002. The other RPOs (Midwest, Western Regional Air Partnership [WRAP] and Mid-Atlantic/Northeast Visibility Union [MANE-VU]) did not have CEM data readily available and/or correct and updated crosswalks for the CEM units for a current year 2002 inventory for their particular region. Only VISTAS met these requirements. The Midwest and MANE-VU RPOs are still generating their updated year 2002 point source inventories (September-November 2004), therefore updated crosswalks had not been generated. Several RPOs (e.g., Midwest) indicated that they may rely on EPA to create the CEM crosswalk data for their

particular region. We acquired the raw CEM data for the year 2002 for the entire United States region from EPA (Marc Houyoux). If and when the crosswalks become available for the other RPOs regions, CENRAP can then use these crosswalk data along with the raw data for the United States to implement hour-specific CEM data throughout their entire modeling domain.

Software was generated to process the CEM data for years 2000 through 2003 and generate monthly, weekly, and hourly profiles for each of the four seasons in SMOKE-ready format. National Weather Service temperature data were obtained from the University of California, Riverside (UCAR) website at http://dss.ucar.edu/datasets/ds472.0. Meteorological data from years 2000-2002 were obtained from UCAR. Plants subject to EPA CEM requirements are not required to report hourly stack flow rates to EPA. We were unable to find a reliable, consistent source of stack flow data that could be used in generating recommendation for temporal profiles for the year 2002.

Table 15 provides a summary of the CEM crosswalk files and documentation acquired for this project.

Table 15. CEM Crosswalk Files and Documentation

Data	Source	Date acquired or generated	Time Period of Data	Known deficiencies
Year 2000-2003 CEM data for CENRAP states	EPA website	27-Aug-04	Year 2000 thru 2003	None known at time of analysis
Year 2000-2003 CEM reports for CENRAP states	EPA website	15-Sep-04	Year 2000 thru 2004	None known at time of analysis
2002 point source inventory data in draft format	Pechan	19-Aug-04	Year 2002	Updates were received up through the month of Sept 2004.
CEM crosswalk for CENRAP states (final version)	UNC-CEP	27-Oct-04	Year 2002	Missing crosswalk data for some CEM units. Used 2002 point source inventory data for mapping information instead of final SMOKE IDA or inventory file used in emissions modeling
VISTAS RPO CEM data	Alpine Geophysics	24-Aug-04	Year 2002	None known at time of analysis
Year 2002 CEM data for all United States	EPA (Marc Houyoux)	03-Sep-04	Year 2002	None known at time of analysis
NWS 2000-2002 temperature data	UCAR	17-Sep-02	Year 2000 thru 2002	None known at time of analysis

3. QA Review

Carolina Environmental Program (CEP) analyzed the CEM crosswalk generated to match up CEM units with a source in the 2002 point source inventory along with the raw CEM databases to determine which units/sources were not being used due to the lack of crosswalk data and/or

bad or no CEM data. There were data for a total of 775 CEM units in the CENRAP states. We informed CENRAP of all CEM units where we lacked sufficient crosswalk data that emitted over 40 tons per year of NO_x or SO_2. It was also recommended to CENRAP that those units that, (1) emitted less than 40 tons per year, and (2) for which no crosswalk record was available, be omitted. A total of 293 units emitted less than less than 40 tons of NO_x in year 2002. A total of 570 units emitted less than 40 tons of SO_2 in year 2002. Some crosswalk data for these "minor-emitting" units were easily obtainable from the 2002 point source inventory. Initial QA review revealed that CEP would most likely be able to map about 500 CEM units (64% of the total number of the units or about 90% of the total emissions) to the inventory data.

We also compared the CEM data in these raw datasets and versus the reports available at (http://cfpub.epa.gov/gdm/index.cfm?fuseaction=prepackaged.select and http://www.epa.gov/airmarkets/emissions/prelimarp/) to ensure that the data we were going to use to create hour-specific emissions were consistent with these reporting tools.

Software was developed to process the CEM data for years 2000 through 2003 to generate monthly, weekly, and hourly profiles for each of the four seasons in SMOKE-ready format. CEP used the same CEM crosswalk created for the 2002 inventory for these years. If the 2002 CEM crosswalk was not able to match up a major-emitting unit from any of the other three years, this unit would have been flagged and been brought to CENRAP's attention. None of these instances were found. It should be noted that this was a temporal profile analysis task and not a task where SMOKE-ready hour-specific emissions data needed to be created. We spot-checked some of the profiles generated from these raw datasets versus the reports available at EPA websites to ensure that the data reformat process had not introduced any errors.

4. Supplemental Data/Augmentation Procedures

UNC-CEP examined the crosswalks generated at CEP and the raw CEM databases acquired from EPA and determined no changes/augmentations to the raw CEM databases were necessary. We did however inform CENRAP via email on October 12, 2004 of the CEM units we were unable to match to the CENRAP 2002 inventory. We did receive feedback from IA, TX, and MN and were able to create crosswalk records to enable more CEM data to be used for these particular states. If we did not enough information to map a CEM unit to a particular source and we did not receive feedback from CENRAP states, then the emissions data for these CEM units were not used to generate hour-specific emissions data for SMOKE. To help keep track of the changes to the CEM crosswalks and other ancillary data used for the processing of the CEM data, these data were checked into Concurrent Versions System (CVS).

The year 2000, 2001 and 2003 CEM data were also examined and spot-check comparisons were carried out using the CEM unit reports also available on the EPA website. It was determined that the CEM data did not need any changes/augmentations in order to perform the temporal profile analysis.

5. QA Review of Final Data Set

CEP analyzed the CEM crosswalk generated after receiving feedback from the CENRAP states to ensure that only changes made were due to new information received. We also determined again which units/sources were not being used due to the lack of crosswalk data and/or bad or no CEM data. Table 16 lists the CEM units that emitted over 40 tons per year of NO_x or SO_2 that could not be identified in the 2002 point source inventory.

Table 16. CEM Units for which Matches to Emission Units could not be Identified in State Inventories

ORISPL ID	Plant Name	STATE	REGION	UNITID	2002 SO_2	2002 NOx
000202	Carl Bailey	AR	6	01	380.3	147.8
000170	Lake Catherine	AR	6	1	0.1	43.5
000170	Lake Catherine	AR	6	2	0.1	53.1
000170	Lake Catherine	AR	6	3	0.2	52.4
000170	Lake Catherine	AR	6	4	3.8	1421.0
055075	Pine Bluff Energy Ce	AR	6	CT-1	11.1	228.0
001175	Pella	IA	7	CS67	413.7	281.7
055117	R S Cogen	LA	6	RS-5	0.7	53.5
055117	R S Cogen	LA	6	RS-6	0.6	48.8
002241	C W Burdick	NE	7	B-3	0.2	76.3
002291	North Omaha	NE	7	CS000A	5,030.0	2661.3
002291	North Omaha	NE	7	4	2,604.8	1,530.4
002291	North Omaha	NE	7	5	3,874.4	1,916.3
055098	Frontera Power Facil	TX	6	1	1.6	87.8
055098	Frontera Power Facil	TX	6	2	1.4	76.2
	Total				**12,323.0**	**8,678.1**

The CEM data associated with the CEM units in the table above could not be used due to insufficient mapping information. This represents a very small portion of the total emissions emitted in year 2002 by the units in the CENRAP states. According to EPA CEM emissions reports, about 1.50 million tons of SO_2 and 0.90 million tons of NO_x were emitted by the CEM units in the CENRAP states. In summary, CEP was able to map 567 of the total 775 units (or 73%) to the inventory data. This translated to successfully mapping 1.49 millions tons of SO_2 emissions (or 99.3% of the total SO_2 emissions) and 0.89 million tons of NOx emissions (or 98.9% of the total NO_x emissions). However, it should be noted that the initial mapping was carried out using the draft point source inventory. During December 2004, the SMOKE IDA inventory files became available to CENRAP. The CENRAP Emissions Modeling contractors began using the SMOKE IDA point source inventory with the SMOKE-formatted hour-specific data created at UNC-CEP. A few CEM (hour-specific) sources were found to be incorrectly mapped during SMOKE processing and, therefore, the hour-specific data could not be used. UNC-CEP corrected the identification information in the hour-specific data so these sources will be correctly mapped to the SMOKE IDA point source inventory. UNC-CEP delivered a new version of the SMOKE hour-specific files to CENRAP on January 27, 2005.

We also carried out spot-checks of the CEM data in the raw datasets and the hourly-emissions files generated (SMOKE hour-specific and RPO formatted files) versus the reports available at (http://cfpub.epa.gov/gdm/index.cfm?fuseaction=prepackaged.select and http://www.epa.gov/airmarkets/emissions/prelimarp/) to ensure that the data created were consistent with these reporting tools.

The final version of the SMOKE-ready and RPO formatted hour-specific files for all days in the year 2002 were sent and received at CENRAP on October 28, 2004. The data were sent via CD and also included the VISTAS RPO and EPA CEM data for the year 2002.

6. Temporal Profile Analysis

UNC-CEP obtained year 2000, 2001 and 2003 CEM data from USEPA (http://cfpub.epa.gov/gdm/index.cfm?fuseaction=prepackaged.select) and also used the year 2002 CEM data mentioned in section E-1 to develop three (3) sets of temporal profiles for each individual unit. The sets of profiles are seasonal profiles, daily profiles by season, and hourly profiles by season. This analysis was performed for units in the CENRAP region that includes the following states: AR, IA, KS, LA, MN, MO, NE, OK, and TX. These profiles could then be used by CENRAP in future emission inventory/modeling applications.

Since emissions preprocessors can now support many thousand different temporal profiles (e.g., SMOKE can handle 99999 different profiles), we prepared individual boiler emission profiles for each of the CEM units in the states listed above. A total of 568 units were included in the preliminary analysis. At CENRAP's request, these individual unit emission profiles were prepared based on combined CEM data from years 2000, 2001 and 2002. We also included year 2003 CEM data to add more relevant and recent data to the analysis. The emission profiles were all based on the NO_x emissions only. There was little difference between the NO_x and SO_2 profiles, with the exception that a good percentage of number of the units had zero SO_2 emissions. We also targeted the analysis on the major-emitting units which was defined as units emitting at least 1 ton of NO_x per average day. This limitation allowed us to focus the analysis on the 344 "major-emitting" units (see Table 17). Three sets of individual unit profiles were prepared: emission fractions by month, emission fractions by day of the week, and emission fractions by hour of the day for a weekday, Saturday, Sunday, and weekend (Saturday and Sunday combined). Software was created to generate these profiles for each of the four seasons in SMOKE-ready format.

Table 17. Number of Units In Each State Where Temporal Profiles Were Generated

State	CEM units
Arkansas	12
Iowa	30
Kansas	21
Louisiana	30
Minnesota	26
Missouri	36
Nebraska	13
Oklahoma	30
Texas	146
Total	**344**

For the monthly emission profiles, the NO_x emissions were totaled by unit and month. The NO_x emissions from each unit for a given month were then divided by the total of the year 2000-2003 NO_x emissions from that unit. For the day of week profiles, the Gregorian date for each hourly CEM data record was converted to the corresponding Julian date. Then, I/OAPI libraries were used to assign day of the week (Monday, Tuesday, etc.) based on the Julian date. Next, NO_x emissions were totaled by day of the week for each unit. The NO_x emission totals at a given unit for each day of the week were normalized by dividing by the sum of the year 2000 through 2003 NO_x emission total for that unit. Similarly, NO_x emissions were totaled by hour and unit for all weekdays, Saturdays, Sundays and weekend days. The hourly profiles were also normalized by dividing by the sum of each hour for each particular day of interest for the 4-year CEM dataset. All profiles were based on local standard time data. This normalization technique was carried out for each of the four seasons (winter, spring, summer and fall) were the seasons were defined as follows:

- Winter–January, February; and March
- Spring–April, May and June
- Summer–July, August and September
- Fall– October, November and December

Previous CEM/temporal analysis studies (Pechan, 2003) have strived to generate a small set of temporal profiles to use for all units over a certain geographical area. While this is possible for this task, we recommend the profiles for the individual units be used. Each unit has many factors that effect temporal allocation of emissions including geographical region, seasonal demands and controls, population and technology changes, costs, and variations in weather from year to year. Emissions preprocessors can handle thousands of different profiles, therefore we recommend that these various factors be captured using the profiles for the individual units.

Figures 1 and 2 give examples of the monthly profiles generated from the 2000-2003 CEM data for the states of AR and NE. Figure 3 is an example of the weekly profiles generated for Arkansas for all four seasons. Figures 4 and 5 give example hourly profiles for Big Brown unit #1, TX and Dolet Hills unit #1, LA respectively. These are just samples of the numerous profiles

generated. All profiles delivered to CENRAP can easily be displayed by importing to MS Excel or other spreadsheet software.

National Weather Service temperature data were also obtained from UCAR (http://dss.ucar.edu/datasets/ds472.0/) for the time period of year 2000-2003. UNC-CEP continues to carry out the analysis of this data in order to determine its usefulness and/or its ability to provide better profile data than the individual unit profiles. We will provide our feedback on this analysis in the next version of this report. UNC-CEP also searched for reliable hourly stack flow databases. Hourly stack flow is not a required element to be reported to USEPA. Therefore, we did not find it on USEPA websites. We were also unable to find an hourly stack flow database that covered the desired years and region of interest.

F. Temporal, Speciation, and Spatial Allocation Profiles

1. Temporal Profiles for Point, Area, and Nonroad Sources

a. Data Sources (e.g., CEM)

CEP obtained the best available temporal profile data for emissions modeling from EPA (see also http://www.epa.gov/ttn/chief/emch/temporal/index.html), RPOs (e.g., MANE-VU), and other source-specific reports/databases (e.g., CEM data). A similar review of temporal profiles for the MANE-VU RPO and the EPA yielded the temporal profiles to be used in the review of the CENRAP emissions inventory dataset. This subsection describes the profile databases used for each component of the CENRAP emission inventory.

Point Sources

A similar review was carried out using the latest temporal profile dataset acquired from EPA on the MANE-VU inventory. Additional profiles were added during this review to support MANE-VU state- or county-specific point sources. We began the CENRAP review using the product (temporal profiles) of this MANE-VU EI review.

Additionally, the CEM data for the years 2000, 2001, 2002 and 2003 were used to come up with 4-year average temporal profiles for each major emitting unit (see also section E of this report). The CEM data were acquired from the following EPA website: http://cfpub.epa.gov/gdm/index.cfm?fuseaction=prepackaged.select.

The CENRAP emissions inventory was provided to us by Pechan in NIF 3.0. Additional data acquired from Pechan included periodic updates to the CENRAP inventory and complete listing of the SCCs in the inventory databases.

Figure 1. Arkansas CEM unit monthly profiles based on year 2000-2003 data.

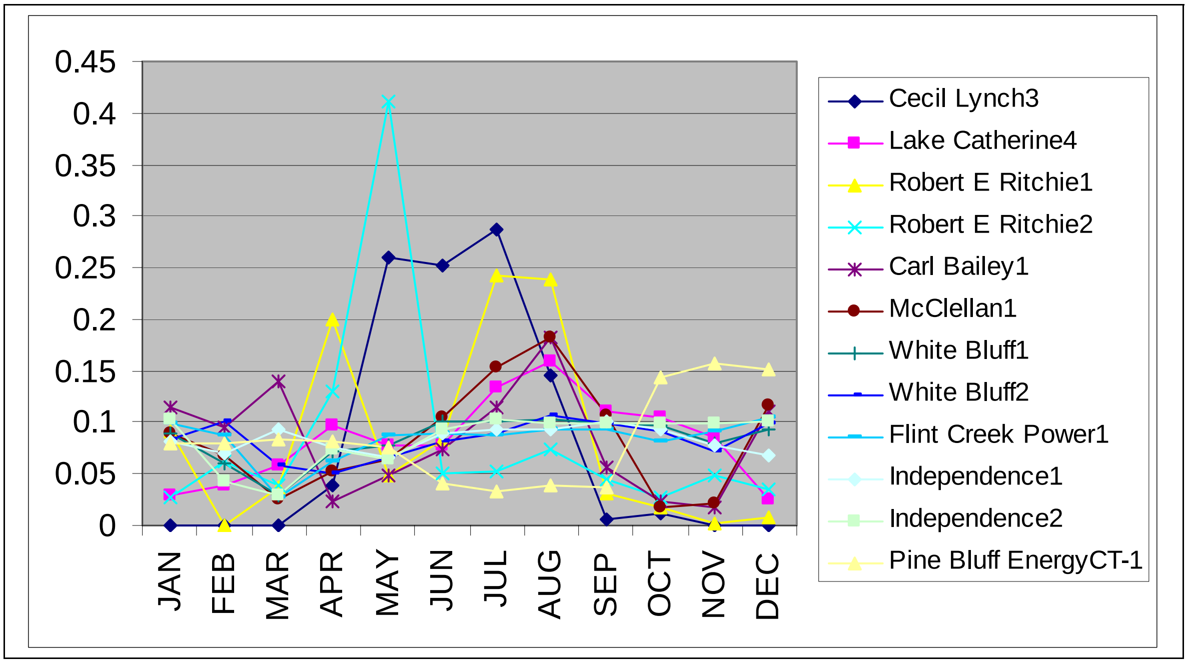

Figure 2. Nebraska CEM unit monthly profiles based on year 2000-2003 data.

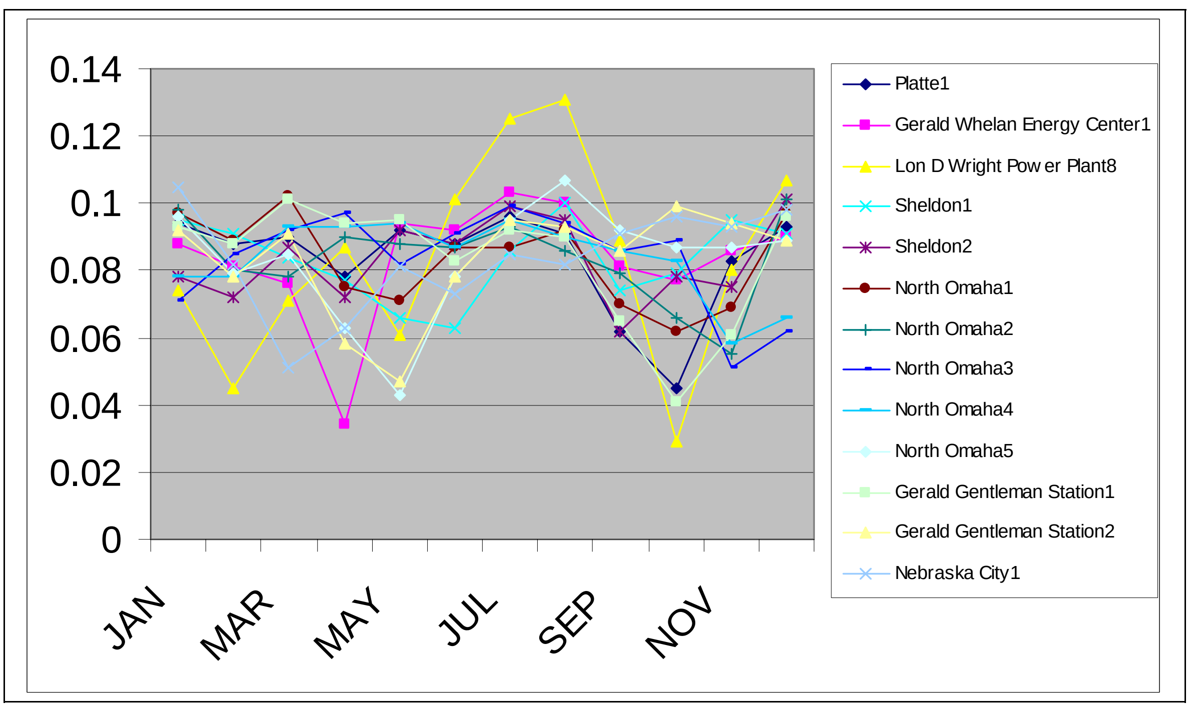

Figure 3. Arkansas weekly profiles for (a) winter, (b) spring, (c) summer and (d) autumn using the 2000-2003 data.

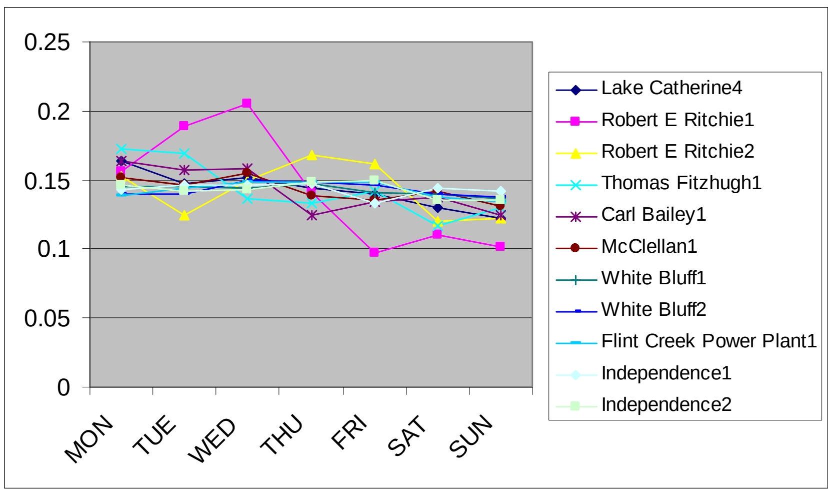
(c)



(d)

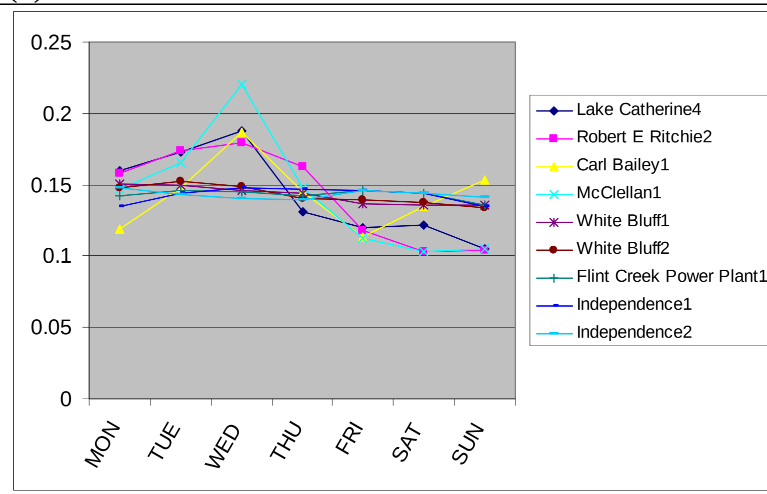


Figure 4. Big Brown Unit 1, Texas hourly profiles for winter for 2000-2003 data.

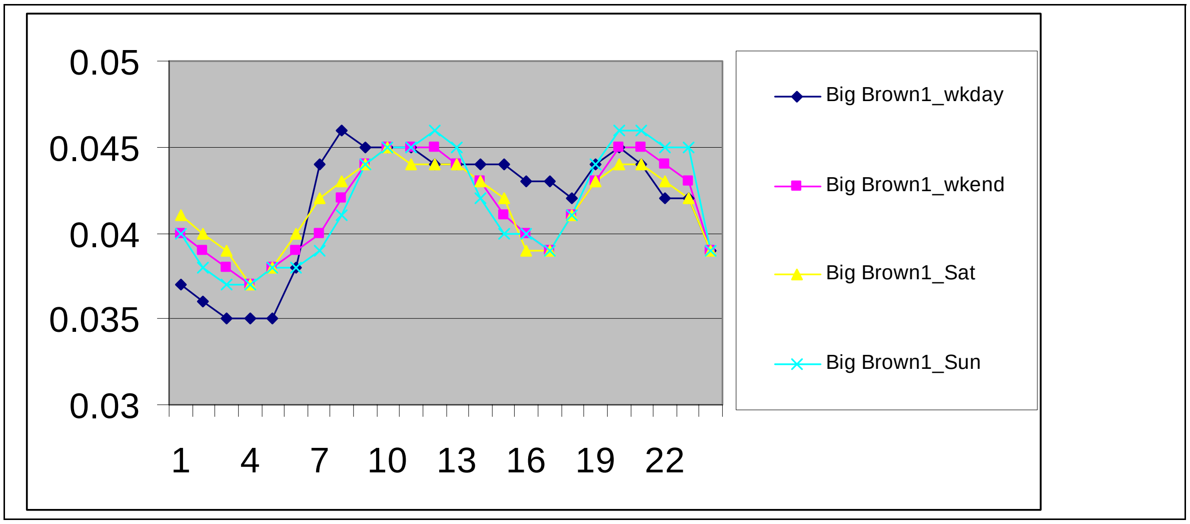

Figure 5. Dolet Hills Unit 1, Louisiana hourly profiles for autumn for 2000-2003 data.

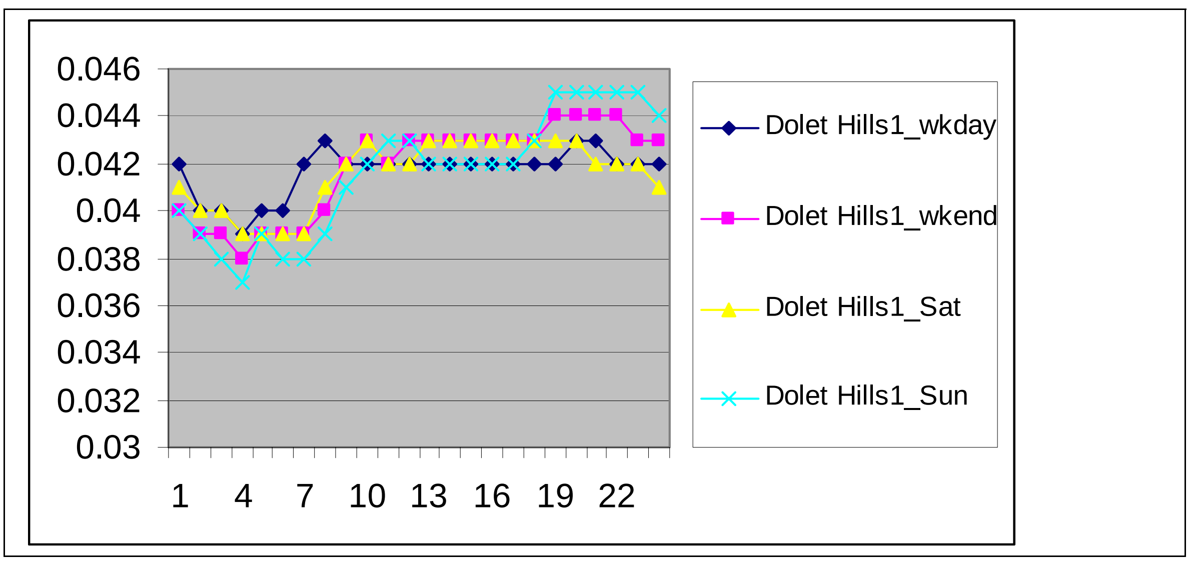

Area and Nonroad Sources

A similar review was carried out using the latest temporal profile dataset acquired from EPA on the MANE-VU inventory. Additional profiles were added during this review to support MANE-VU state- or county-specific area and nonroad sources. We began the CENRAP review using the product (temporal profiles) of this MANE-VU EI review.

Additionally, we used the final report (STI, 2003) generated for NH_3 emissions inventories to aide in the coming up with applicable temporal profiles for use with the CENRAP emissions inventory.

b. Supplemental Data/Augmentation Procedures

A cross-reference table is necessary in order to appropriately apply the desired temporal profile to a certain emission source. This assignment or cross-reference is typically made by SCC, but can also be made for a specific FIPS-SCC combination or all SCCs in a FIPS region combination. For point sources, emissions modelers can also assign a specific temporal profile by a specific unit, stack, and/or facility identification. We conducted the review of CENRAP emissions inventory using the most recent temporal cross-reference table available that was the table generated during the MANE-VU review.

CEP identified SCCs that did not have a specific temporal profile assigned in the temporal cross-references file used in recent EPA and RPO applications. CEP created a new temporal cross-reference to an existing profile in the default SMOKE profiles for SCCs in the CENRAP; the cross-reference did not previously exist in the cross-reference file used at the beginning of the review (see Data Sources section) but the profile did exist.

All of the improvements to the SMOKE temporal cross-reference file and profiles that are summarized in this memo are included in the files *amptref.m3.cenrap.102804.txt* and *amptpro.m3.us+can.cenrap.102804.txt*, which were included as an electronic docket and delivered on October 28, 2004.

Table 18 summarizes the updates to entries in the default SMOKE cross-reference file for point sources and Table 19 for area/nonroad sources. The commonly assigned monthly profile is monthly profiles is 262 = uniform monthly. The most common weekly profiles are 7 = 'uniform emissions throughout the week' weekly and 5 = 'emit weekdays only' profile. The most common diurnal profiles are 12 = 12 hours per day during daylight hours and 26= maximum middle of the day; minimum early in morning. See the *amptpro.m3.us+can.cenrap.102804.txt file* for specific definitions of each profile.

These changes to the temporal cross-reference file have allowed us to apply a non-flat temporal profile (262= uniform monthly, 7=uniform weekly and 24=uniform diurnal) to ~90% of the SCCs in the point source inventory and ~95% of the SCCs in the area/nonroad source inventory. This is the best we could do with the information available to us at the time of the analysis.

Table 18. New Temporal Profile Assignments for CENRAP Point Source SCCs

State	SCC	Recommended Monthly, Weekly, and Diurnal Profiles			Method of Assignment	SCC Description

We will augment the temporal profiles and cross-references delivered on Oct 28, 2004 with NH_3-specific temporal profiles using the STI final report on NH_3 sources. This will include monthly profiles for Texas and Arkansas and diurnal profiles for all states for applicable SCCs. The delivery of these profiles/cross-references is scheduled for early January 2005. The temporal profiles for each major emitting CEM unit based on a 4-year average (data from 2000 through 2003) were also delivered to CENRAP in January 2005.

2. Speciation Profiles for Point, Area, and Nonroad Sources

a. Data Sources

CEP obtained the best available speciation profile data for emissions modeling from EPA for the CB-IV with PM mechanism (see also http://www.epa.gov/ttn/chief/emch/speciation/index.html). The CENRAP emissions inventory was provided to us by Pechan in the NIF 3.0. Additional data acquired from Pechan included periodic updates to the CENRAP EI and complete listing of the SCCs in the inventory databases.

b. Supplemental Data/Augmentation Procedures

A cross-reference table is necessary in order to appropriately apply the desired speciation profile to a certain emission source. This assignment or cross-reference is typically made by SCC, but can also be made for a specific FIPS-SCC combination or all SCCs in a FIPS region combination. For point sources, emissions modelers can also assign a specific temporal profile by a specific unit, stack, and/or facility identification. We conducted the review of CENRAP emissions inventory using the most recent speciation cross-reference table available which was the table generated during the MANE-VU review.

Several SCCs in the CENRAP EI did not have chemical speciation profile assignments for the CB-IV with PM mechanism in the default SMOKE chemical cross-reference file. CEP added assignments for VOC speciation for the SCCs listed in Table 20 (area/nonroad sources) and Table 21 (point sources) to the speciation cross-reference file for compatibility with the CENRAP EI. The recommendations for these assignments are based on the speciation profile codes assigned to similar SCCs. We attempted to match the SCCs as accurately as possible, i.e. we looked for the closest SCC possible to supplement the missing assignment. The new chemical profile assignments were added to the file *gsref.cmaq.cb4p25.cenrap.102804.txt.* We did not make any changes to the speciation profiles file.

Please note that we understand that Pechan will soon be delivering some new PM and VOC profiles to EPA that are being incorporated into SPECIATE. Since some of these will have important implications for regional haze modeling, CENRAP may want to consider having these included in the modeling inventory. These profiles would take additional effort not already in the planned scope of work to implement. Some of the more important profiles will cover:

- Commercial Cooking (PM and VOC);
- Distillate and Natural Gas Fired Boilers (PM);
- Paved and Unpaved Road Dust;

- Motor Vehicle Exhaust/Tire Wear/Brake Wear; and
- Wildfires/Prescribed Burns.

Table 20. VOC Speciation Profiles Assigned to Area Source SCCs

SCC	Description	VOC	Recommendation Based on Profile Data for SCC	Description of Similar SCCs used to Recommend Profiles
2310001000	Industrial Processes;Oil and Gas Production: SIC 13;All Processes : On-shore;Total: All Processes	9015	2310000000	Industrial Processes;Oil and Gas Production: SIC 13;All Processes;Total: All Processes

3. Spatial Allocation Profiles for Area and Nonroad Sources

a. Data Sources

CEP obtained the best available spatial profile data for emissions modeling from EPA for the geographical area covered by the CENRAP 36-kilometer modeling domain (http://www.epa.gov/ttn/chief/emch/spatial/newsurrogate.html). A detailed description of this surrogate dataset is available at: http://www.epa.gov/ttn/chief/emch/spatial/new/surrogate_documentation_workbook052804.xls.

The CENRAP emissions inventory was provided to us by Pechan in the NIF 3.0. Additional data acquired from Pechan included periodic updates to the CENRAP EI and complete listing of the SCCs in the inventory databases.

b. *Supplemental Data/Augmentation Procedures*

A cross-reference table is necessary in order to appropriately apply the desired spatial allocation profile to a certain emission source. This assignment or cross-reference is typically made by SCC, but can also be made for a specific FIPS-SCC combination or all SCCs in a FIPS region combination. We conducted the review of CENRAP emissions inventory using the most recent speciation cross-reference table available which was the table generated during the MANE-VU review.

Several SCCs in the CENRAP area source EI did not have surrogate assignments in the default SMOKE gridding cross-reference file. These SCCs would be assigned the default surrogate which is population when spatially allocating emissions in emissions processing applications. CEP added spatial profile assignments for the SCCs listed in Table 22 to the gridding cross-reference file for compatibility with the CENRAP EI. The recommendations for these assignments are based on matching surrogate descriptions from the EPA surrogate data descriptions (see http://www.epa.gov/ttn/chief/emch/spatial/new/surrogate_documentation_workbook052804.xls) with the SCC descriptions. The new surrogate assignments were added to the file *amgref.m3.us+can+mex.cenrap.102804.txt* and included as part of the electronic docket delivered on October 28, 2004. CENRAP contractors already have a surrogate dataset for the 36-kilometer modeling domain using the EPA surrogate database. We are awaiting final definition of the CENRAP 12-kilometer domain(s) before delivering spatial surrogates to CENRAP.

Table 22. Surrogate profiles assigned to SCCs to support CENRAP EI

SCC	Description	Surrogate profile	Surrogate Description
2310001000	Industrial Processes;Oil and Gas Production: SIC 13;All Processes : On-shore;Total: All Processes	585	Metals and Minerals Industrial (IND4)
2310002000	Industrial Processes;Oil and Gas Production: SIC 13;All Processes : Off-shore;Total: All Processes	585	Metals and Minerals Industrial (IND4)
2311000000	Industrial Processes;Construction: SIC 15 - 17;All Processes;Total	140	Housing Change and Population
2461022999	Solvent Utilization;Miscellaneous Non-industrial: Commercial;Emulsified Asphalt;Solvents: NEC	140	Housing Change and Population
2461870999	Solvent Utilization;Miscellaneous Non-industrial: Commercial;Pesticide Application: Non-Agricultural;Not Elsewhere Classified	515	Commercial plus Institutional Land

2810040000	Miscellaneous Area Sources;Other Combustion;Aircraft/Rocket Engine Firing and Testing;Total	700	Airport Area

4. QA Review of Final Data Sets

Table 23 lists the spatial, temporal and speciation allocation profiles and cross-reference tables, technical memoranda and other ancillary data delivered to CENRAP on October 28, 2004. Table 24 lists the sources and other attributes of the ancillary data collected and reviewed including the temporal profiles generated using the CEM data for years 2000-2003. All of the data files were QA reviewed twice by ensuring that no default profiles are being used and the data are in the correct format for use in the emissions models. The following data may be updated in early 2005 to incorporate more recent information:

- NH_3 temporal profile updates
- Spatial surrogates for the 12- kilometer modeling domain(s) once defined by CENRAP
- 4-year average temporal profiles for each major emitting CEM unit

These data will also be quality assured in a similar manner (no default profiles being used, correct format, etc.). Most of the data presented in this section have been delivered with a few additional data sets to be delivered in January 2005. These additional data sets are mentioned in this section. The next version of this report will include any necessary documentation associated with the supplemental deliverables.

G. Preparation of SMOKE/IDA and RPO Data Exchange Protocol (NIF 3.0) Formats

This section describes the inventory and SMOKE emission processor files prepared under this project. The Excel Workbook file named "CENRAP Inventory File Documentation _030405.xls" provides the names of the files delivered, as well as other file information useful for transferring data to air quality modeling centers. This Excel Workbook file is provided along with this report. The following Table 25 provides a summary of the files delivered.

The ancillary data (described in section F) that are necessary input for emissions preprocessors have been formatted for use in SMOKE and in the RPO Data Exchange Protocol format. Table 26 lists the profiles, cross-reference tables, and other ancillary data (SCC descriptions) that have been provided to CENRAP. The data have undergone a review which is described in section F and in technical memoranda sent to CENRAP on October 28, 2004.

Table 25. Summary of Mass Emissions and SMOKE Input Files

S/L/T Agencies Included in Files	NIF 3.0 File Name Containing Mass Emissions Inventory (Access 2000 Database Files)	Temporal Period of Mass Emissions Inventory	SMOKE/IDA File Name	Temporal Period of Emissions in SMOKE/IDA File	Notes
Point Source Inventory					
AR, IA, KS, LA, MN, MO, NE, OK, TX, Local, and Tribal	CENRAP_2002_Point_021605.mdb	Annual	CENRAP_POINT_SMOKE_INPUT_ANNUAL_DAILY_021805.txt	Annual for all agencies; Daily for MO and TX	Includes all sectors supplied by S/L/T agencies. Tribal inventory is for Fond du Lac Band of the Minnesota Chippewa Tribe. Local inventories include Lancaster County (Lincoln) and Douglas County (Omaha), NE
MO and TX	CENRAP_2002_Point_Daily_Missouri_Texas_20050216.mdb	Daily	CENRAP_POINT_SMOKE_INPUT_ANNUAL_DAILY_021805.txt	"	Daily emissions for MO and TX are included in the SMOKE/IDA file containing annual emissions for all CENRAP agencies, but placed in a NIF 3.0 file separate from the NIF 3.0 file containing the annual emissions.
Nonroad Source Inventory					
AR, IA, KS, LA, MN, MO, NE, OK, TX	CENRAP_2002_Nonroad_030305.mdb	Annual and Daily	CENRAP_NONROAD_SMOKE_INPUT_ANN_STATE_030405.txt	Annual	Includes NONROAD Model Categories and Aircraft, Commercial Marine Vessels, and Railroad Locomotives. NONROAD Model inventory is from CENRAP-sponsored inventory except for TX who supplied its own NONROAD Model Inventory. MN included commercial and military aircraft and auxiliary power units in its point source inventory; therefore, the nonroad inventory does not contain emissions for these categories in MN.
Area Source Inventory					
AR, IA, KS, LA, MN, MO, NE, OK, TX	CENRAP_2002_Area_022205.mdb	Annual, Daily, and Monthly	CENRAP_AREA_SMOKE_INPUT_ANN_STATE_022205.txt	Annual	Includes all sectors except for those included in the Area Misc files. Planned burning emissions from CENRAP-sponsored area source inventory are excluded for IA, KS, LA, MN, MO, OK, and NE (except for Lancaster County [FIPS 31109]); the SMOKE files for the CENRAP planned burning inventory will be used for these states.
IA, KS, LA, MN, MO, NE, OK	"	"	CENRAP_AREA_SMOKE_INPUT_NH3_MONTH_JAN_120304.txt	Monthly Emissions x 12	All sectors except for those included in the Area Misc files. Monthly emissions are multiplied by 12 (months).
IA, KS, LA, MN, MO, NE, OK	"	"	CENRAP_AREA_SMOKE_INPUT_NH3_MONTH_FEB_120304.txt	Monthly Emissions x 12	All sectors except for those included in the Area Misc files. Monthly emissions are multiplied by 12 (months).
IA, KS, LA, MN, MO, NE, OK	"	"	CENRAP_AREA_SMOKE_INPUT_NH3_MONTH_MAR_120304.txt	Monthly Emissions x 12	All sectors except for those included in the Area Misc files. Monthly emissions are multiplied by 12 (months).

Table 25 (continued)

III. SUMMARIES OF EMISSIONS INVENTORIES FOR THE CENRAP REGION

Summaries of emissions were prepared from the emission inventory files for each sector and for all sectors combined. The summaries are provided in an Access 2000 database named "CENRAP Emission Summaries_030805.mdb". Table 27 identifies and briefly describes the contents of the emissions summary tables included in the database. The nonroad source sector summaries include emissions for aircraft, commercial marine vessels, and locomotives as well as the emissions from the NONROAD model categories. The onroad summaries were prepared from the CENRAP-sponsored inventory for onroad sources. Tables 1G, 2C, 3C, 4C, and 5C include the data source code for the area, point, nonroad, and onroad sectors to assist in identifying the origin and year of emissions inventory data. The data source codes were defined previously in Chapter II of this report.

The summaries in Appendix A of this report are taken from the emissions summary Table 2D. However, emissions summary Table 2D includes natural sources/biogenic NH_3 emissions and geogenic PM10-PRI and PM25-PRI emissions. The biogenic and geogenic emissions were excluded from the summary tables included in Chapter I of the report. Thus, the biogenic and geogenic emissions were excluded from the NH_3 and PM10-PRI and PM25-PRI summaries in Appendix A so that the total emissions in the Appendix A summaries match the total emissions in the summaries in Chapter I of the report.

IV. METHODS FOR AREAS OUTSIDE OF THE CENRAP REGION

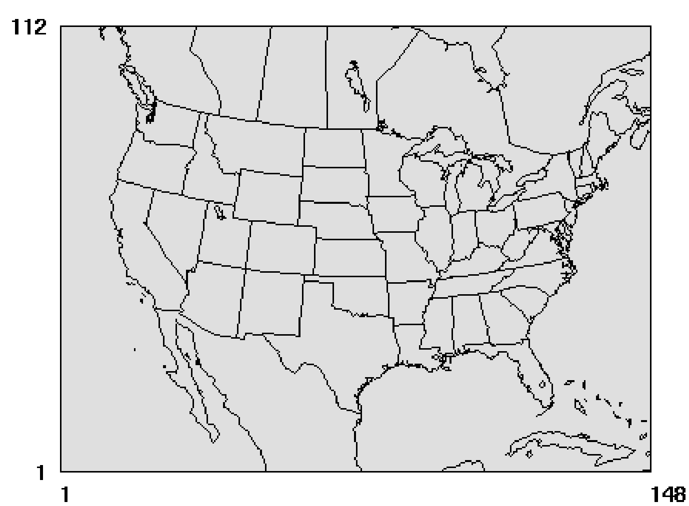
A. Data Sources

This task involved gathering and consolidating point and area source emissions data for areas outside the CENRAP region. The sources of data included emissions inventories compiled by the other RPOs, the EPA, Environment Canada, Texas Commission on Environmental Quality (TCEQ), and other applications (e.g., Big Bend Regional Aerosol and Visibility Observational (BRAVO)). CENRAP indicated to UNC-CEP the definition of the 36-kilometer modeling domain would have the following definition:

NCOLS = 148
NROWS = 112
GDTYP = 2 (Lambert conformal)
P_ALP = 33.
P_BET = 45.
P_GAM = -97.
XCENT = -97.
YCENT = 40.
XORIG = -2736000.
YORIG = -2088000.
XCELL = 36000.
YCELL = 36000.

This modeling domain definition is also illustrated in Figure 6.

Figure 6. The CENRAP 36-kilometer modeling domain.



We used this 36-kilometer domain definition to come up with the geographical areas outside of the CENRAP states where inventory data are needed for CENRAP modeling applications.

We contacted the VISTAS and WRAP RPOs and were able to acquire year 2002 point, area and nonroad inventory data for their respective states. The data acquired was being used in their most recent modeling applications, however they did inform us that updates to the 2002 inventory are likely in near future. As of late December 2004, the Midwest RPO did not have a "final" version of their 2002 inventory to release for use by other RPOs. MANE-VU RPO's point, area, onroad, and nonroad inventories were finalized at the end of January 2005 and made available to other RPOs in February 2005.

The Mexican inventory databases available were the 1999 inventory used in the BRAVO modeling application and an updated inventory being developed by another contractor (Eastern Research Group [ERG]). We were not able to obtain the updated inventory from ERG. Moreover, the point source inventory will most likely be proprietary and could require a non-discloser agreement. Since we could not obtain this data, we recommend using the BRAVO inventories for the areas of the CENRAP modeling domain(s) that includes regions of Mexico.

The Canadian inventory databases from Environment Canada available are a 1995 inventory and a recently release year 2000 inventory. The point source data are proprietary, therefore, the data for year 2000 were not immediately available and the 1995 point source inventory can't be used by CENRAP unless their contractors get permission from Environment Canada to do so. However, we were able to obtain the area, nonroad, and mobile source inventories for the year 2000 from Environment Canada. We were able to reformat the data for use in SMOKEv2 and produce emissions total reports. These reports did not match up with the emission inventory totals Environment Canada provided with the data. The EPA and UNC-CEP found many problems with the year 2000 data including a lack of subprovince codes for better spatial allocation of emissions and different set of SCCs in the ASCII version of the inventory vs. the Microsoft Access version of the inventory. We reported these issues to Environment Canada and very recently (late December 2004) received another version of this inventory. We are now beginning to QA this new version. However, we recommend using the year 1995 area, nonroad and mobile source inventories until confidence in the year 2000 data can be acquired.

The Minerals Management Services (MMS) recently released a year 2000 Gulfwide Emissions Inventory (GWEI) which is available at the following website:

http://www.gomr.mms.gov/homepg/regulate/environ/airquality/gulfwide_emission_inventory/2000GulfwideEmissionInventory.html

This inventory dataset includes platform (treated as point sources) and non-platform (treated as area sources) sources for most of the Gulf of Mexico. TCEQ and other contractors (Environ and ERG) provided UNC-CEP with ancillary and sample MMS inventories for an average August 2000 day in Emissions Preprocessor System version 3 (EPS3) format. UNC-CEP was able to use these ancillary data and the raw MMS data to create annual inventory in SMOKE IDA format for the non-platform sources and an average August 2000 inventory in SMOKE IDA format for the platform sources. Generating an annual platform inventory will require additional

ancillary data to be acquired from TCEQ. TCEQ is working on providing this data. UNC-CEP will generate the year 2000 annual inventory for platform sources as soon as this ancillary data are acquired. Additional ancillary data necessary in order to use the MMS SMOKE IDA inventories in emissions modeling were also generated. This ancillary data includes spatial surrogates for the CENRAP 36-kilometer grid (Figure 6), temporal profiles, and spatial and temporal cross-references. These data have been provided to CENRAP for use in emissions modeling applications for both the non-platform and platform inventories. Additional technical details about these MMS inventories were provided with the data to help emissions modelers understand and properly apply the inventory and ancillary data.

All of the data and associated emissions summaries described in this section were delivered to CENRAP on December 27, 2004. Table 28 provides a list of the deliverables, the date acquired, the sources used to assemble the data, the contractor(s) and/or organizations that assembled the data, possible deficiencies of the data, time period of the data (e.g., year 2002), and other necessary information needed to enable CENRAP to best understand the databases that are available. Draft summaries of point and area source emissions data for these data obtained for areas outside of CENRAP were generated and provided with the December 27, 2004 deliverables.

B. Supplemental Data/Augmentation Procedures

The supplemental data needed to run SMOKE were provided to CENRAP and described in detail in section F of this report. Additional ancillary data to support the data sets described in the previous section (IV.A) were provided to CENRAP on December 27, 2004. This mainly included specific spatial profile and cross-references and temporal cross-references for the Minerals Management Service (MMS) inventories, but also included better default stack parameters for Mexican point sources. Table 29 includes a listing of all files provided to CENRAP on December 27, 2004.

Table 28. Description of Inventory Data Provided to CENRAP

Geographic Region/RPO	Raw Data	Time Period	Raw Data Format	Date Received	Source of Data	Source of Ancillary Data	Possible Deficiencies	Date Data and Summaries Delivered to CENRAP
VISTAS	Point, area and nonroad	2002	SMOKE IDA	24-Aug-04	Gregory Stella, Alpine Geophysics	Gregory Stella, Alpine Geophysics	Possibly updated inventory coming soon	27-Dec-04
WRAP	Point, area and nonroad	2002	SMOKE IDA	1-Dec-04	Tom Moore, Colorado St and Zac Adelman, UNC-CEP	Tom Moore, Colorado St and Zac Adelman, UNC-CEP	Possibly updated inventory coming soon	27-Dec-04
Mexico	Point, area, nonroad and mobile	1999	SMOKE IDA	Early 2002	Hampden Kuhns, Desert Research Institute	Jeff Vukovich, UNC-CEP	1999 specific; updated Mexican inventory available from ERG soon?	27-Dec-04
Canada	Area, nonroad and mobile	2000	SMOKE IDA	Jan 12, 2005	ftp://ftp.epa.gov/pub/EmisInventory/canada_2000inventory/. USEPA via Env. Canada	UNC-CEP	New inventory; not well tested in AQ modeling applications.	12-Jan-05
Gulf of Mexico	Point, area and nonroad	2000	MS Access	18-Oct-04	MMS website: http://www.gomr.mms.gov/homepg/regulate/environ/airquality/gulfwide_emission_inventory/2000GulfwideEmissionInventory.html	Jim MacKay and Ron Thomas, TCEQ and Richard Billings, ERG	2000 specific; platform inventory is based on average August day	27-Dec-04
MARAMA	Area, nonroad and point	2002	SMOKE IDA	Last updated Feb 15, 2005	http://www.marama.org/visibility/Inventory%20Summary/2002EmissionsInventory.htm	MARAMA website/ EH Pechan	Unknown since updated recently.	15-Feb-05

Pechan, 2003: Analysis of Utility Emissions Tracking System/Continuous Emissions Monitoring (ETS/CEM) Data, Final Report. Prepared by E.H. Pechan & Associates, Inc., (Pechan Report #03.07.003/9411.000) for the Lake Michigan Air Directors Consortium. July 2003.

STI, 2003: Coe, D. and S. Reid, Sonoma Technology Inc., "Research and Development of Ammonia Emission Inventories for the CENRAP," Final Report STI-902501-2241-FR, October 30, 2003.

Thompson, 2002: Thompson, Rhonda L., "A Demonstration of the Quality Assurance (QA) software specifically developed for the National Emission Inventory (NEI)," presented at the International Emission Inventory Conference "Emission Inventories - Partnering for the Future," Atlanta, GA, April 15-18, 2002, (http://www.epa.gov/ttn/chief/conference/ei11/qa/thompson.pdf).

APPENDIX A

SUMMARIES OF ANNUAL EMISSIONS BY SOURCE CATEGORY, SECTOR, AND POLLUTANT

Table A-1. Summary of Annual VOC Emissions for the CENRAP Region by Category, Sector, and Pollutant

Category	Category Number	Sector	VOC Tons/Year	VOC Percent of Total	VOC Cumulative Percent
Mobile Sources-Highway Vehicles-Gasoline	2201	ON-ROAD	765,838	17.47	17.47
Industrial Processes-Oil and Gas Production: SIC 13	2310	AREA	731,153	16.68	34.15
Mobile Sources-Pleasure Craft	2282	NONROAD	418,585	9.55	43.7
Mobile Sources-Off-highway Vehicle Gasoline, 2-Stroke	2260	NONROAD	208,980	4.77	48.47
Petroleum and Petroleum Product Storage & Transport-Other	250	AREA	189,313	4.32	52.79
Solvent Utilization-Miscellaneous Non-industrial: Consumer and Commercial	24600 - 24	AREA	167,832	3.83	56.62
Industrial Surface Coating	2401015000	AREA	153,472	3.5	60.12
Stationary Source Fuel Combustion-Residential	2104	AREA	143,710	3.28	63.4
Solvent Utilization-Miscellaneous Non-industrial: Commercial	24610 - 24	AREA	128,915	2.94	66.34
Miscellaneous Area Sources-Agricultural Production-Crops-Field Burning	28015	AREA	102,575	2.34	68.68
Petroleum and Solvent Evaporation-Surface Coating Operations	402	POINT	101,968	2.33	71.01
Industrial Processes-Pulp and Paper and Wood Products	307	POINT	95,121	2.17	73.18
Mobile Sources-Off-highway Vehicle Gasoline, 4-Stroke	2265	NONROAD	87,696	2	75.18

I. INTRODUCTION

A. Overview

This report documents the data sources, methods, and results for updating the 2002 base year criteria air pollutant (CAP) and ammonia (NH_3) emissions inventories for point, area, and nonroad sources for the Central Regional Air Planning Association (CENRAP) Regional Planning Organization (RPO). The "Base A" 2002 inventory files completed during February 2005 were updated to incorporate comments provided by the CENRAP State, Local, and Tribal (S/L/T) agencies and the Emissions Inventory (EI) and Modeling Workgroups. As a result of the updates, the new inventory files are termed "Base B". Additional work completed under this work order include the development of Sparse Matrix Operator Kernel Emissions/Inventory Data Analyzer (SMOKE/IDA) input files for a 2018 projection year inventory for electricity generating units (EGUs) and for fires that occurred in Ontario during 2002.

The CENRAP region includes the states and tribal jurisdictions of Arkansas, Iowa, Kansas, Louisiana, Minnesota, Missouri, Nebraska, Oklahoma, and Texas. CENRAP (and other RPOs) will use these inventories to support air quality modeling, State Implementation Plan (SIP) development, and implementation activities for the regional haze rule and fine particulate matter (PM) and ozone National Ambient Air Quality Standards (NAAQS).

The inventories and supporting data prepared include the following:

(1) Comprehensive, county-level, mass emissions and modeling inventories for point, area, and nonroad sources of 2002 emissions for the CAPs and NH_3 for the S/L/T agencies included in the CENRAP region;
(2) Modeling inventory files containing 2018 projection year emissions for EGUs; and
(3) A modeling inventory for Ontario fires during 2002.

The mass emissions inventory files were prepared in the National Emissions Inventory (NEI) Input Format Version 3.0 (NIF 3.0). The modeling inventory files were prepared in the SMOKE/IDA format. The revisions to the Base A point, area, and nonroad inventories did not result in adding any new SCCs that were not already included in the temporal, speciation, and spatial allocation profiles for the CENRAP inventories. Therefore, there were no revisions to the ancillary files containing the spatial, temporal, and speciation profile data.

The inventories include annual emissions for sulfur dioxide (SO_2), oxides of nitrogen (NO_x), volatile organic compounds (VOC), carbon monoxide (CO), NH_3, and particles with an aerodynamic diameter less than or equal to a nominal 10 and 2.5 micrometers (i.e., primary PM_{10} and $PM_{2.5}$). The inventories included summer day, winter day, and average day emissions. However, not all agencies included daily emissions in their inventories, and, for the agencies that did, the temporal basis for the daily emissions varied between agencies. Consequently, the inventories did not contain a complete and consistent set of daily emissions for all source categories and pollutants. Therefore, daily emissions prepared by S/L/T agencies were maintained in the NIF files if they met quality assurance (QA) review requirements. However, CENRAP requested that the daily emissions not be included in the SMOKE input files. The

temporal profiles prepared for this project will be used to calculate daily emissions. If needed, the daily emissions prepared by the agencies may be retrieved from the NIF database files.

The following data sources were used to update CENRAP's Base A inventories:

(1) S/L/T agency comments on the "Base A" inventories;
(2) S/L/T agency comments on the draft 2002 NEI;
(3) Revisions to CENRAP-sponsored inventories; and
(4) Comments from CENRAP's EI and Modeling Workgroups.

The United States (U.S.) Environmental Protection Agency's (EPA's) format and content QA programs (and other QA checks not included in EPA's QA software) were run on each inventory to identify format and/or data content issues (EPA, 2004a). E.H. Pechan & Associates, Inc. (Pechan) worked with the CENRAP's EI and Modeling Workgroups and the S/L/T agencies to resolve QA issues and augment the inventories to fill data gaps in accordance with the Methods Plan and Quality Assurance Project Plan (QAPP) prepared for this project (CENRAP, 2005a; CENRAP, 2005b). The EI Workgroup and S/L/T agencies reviewed the draft inventory files after updating the inventories, and the files were updated to address their comments.

B. Summary of the 2002 Base Year Inventories

This section of the report provides a brief summary of the consolidated 2002 Base B inventories for the CENRAP region. Table 1 shows total annual emissions for CAPs and NH_3 for point, area, nonroad, and onroad sources. The sector contributing the highest emissions varies by pollutant. Point sources account for the highest percentage of total NO_x (35 percent) and SO_2 (83 percent) emissions. Area sources account for the highest percentage of total VOC (44 percent), primary PM_{10} (PM10-PRI (93 percent)), primary $PM_{2.5}$ (PM25-PRI (81 percent)), and NH_3 (83.5 percent) emissions. Onroad sources account for the highest percentage of CO (57 percent) emissions. Onroad sources account for 24.5 percent and nonroad sources account for 17 percent of total VOC emissions. Onroad sources account for 33 percent and nonroad sources account for 18.5 percent of total NO_x emissions.

Table 2a shows total annual emissions by state and pollutant for all four sectors combined. Tables 2b through 2e show total annual emissions by state and pollutant for area, point, nonroad, and onroad sources, respectively. Tables A-1 through A-6 in Appendix A provide summaries of annual emissions by source category and sector for VOC, NO_x, CO, SO_2, PM10-PRI and PM25-PRI, and NH_3, respectively. The emissions in each table are sorted in descending order with the highest emitting categories listed at the top of the table. The tables also show annual emissions as a percentage of total emissions from all sectors, and the cumulative percentage contribution. Chapter III of this report identifies additional summaries of emissions, including county-level summaries that contain the data source codes that identify the origin and year of emissions data.

The Fond du Lac Band of the Minnesota Chippewa Tribe and the Leech Lake Band of Ojibwe Tribe each provided point and area source inventories. The point source inventories are included in the Base B inventory; however, the area source inventories are not because SMOKE is not currently programmed to process tribal area source data. Thus, the tribal area source inventories

are included in a separate NIF 3.0 database and the area source emissions are summarized in Table 2f (note that these area source emissions are not included in Tables 1, 2a, and 2b).

The nonroad Base B inventory includes carbon dioxide (CO_2) emissions, the point source inventory includes total primary and filterable particulate matter (PM-PRI/-FIL) emissions, and the point and area source inventories include filterable PM_{10} (PM10-FIL), filterable $PM_{2.5}$ (PM25-FIL), and condensible PM (PM-CON) emissions. The emissions for these pollutants were carried in the mass emissions inventory files. However, these pollutants are not included in the summaries since the emissions for these pollutants were not consistently reported by all S/L/T agencies for a given sector. In addition, AR is the only state that included PM10-PRI and PM25-PRI emissions for fugitive wind-blown dust emissions in its area source inventory. The wind-blown dust emissions are stored in the area miscellaneous sources inventory, and are included in the sector-level summaries (as geogenic and natural/biogenic sources) described in Chapter III of this report.

C. Organization of the Report

In Chapter II of this report, section A provides an introduction to the chapter and sections B through D present the data sources and methods applied to prepare the mass emissions inventory and SMOKE input files for point, area, and nonroad sources within the CENRAP region. Section E explains the data sources and methods applied to prepare SMOKE IDA files for a 2018 projection year inventory for electricity generating units (EGUs) in the CENRAP region. Section F provides documentation of the SMOKE and RPO data exchange protocol files prepared under this project.

Chapter III and Appendix A provide summaries of the 2002 emissions inventories for point, area, nonroad, and onroad sources within the CENRAP region. Chapter IV presents the data sources and methods applied to prepare SMOKE input files for 2002 fires in Ontario, Canada. Chapter V provides the references for this report.

D. Project Work Plan and Methods Document

At the beginning of this project, a draft work plan and methods document was prepared and reviewed by the CENRAP EI and Modeling Workgroups (CENRAP, 2005a; CENRAP, 2005c). The Workgroups did not provide any comments on these two deliverables. Thus, the draft work plan and methods document was not revised. However, during the duration of the project, the Workgroups requested additional revisions to the Base A point, area, and nonroad inventories after the draft work plan and methods document was prepared and reviewed by the Workgroups. This final report for the Base B inventory details all of the updates and refinements completed on the Base A inventory. However, due to time and resource constraints, the draft work plan and methods document was not revised to reflect this additional work.

II. REFINEMENT OF THE CRITERIA AIR POLLUTANT AND NH_3 INVENTORIES FOR THE CENRAP REGION

A. Introduction

The following data sources were used to update CENRAP's 2002 Base A inventories:

(5) S/L/T agency comments on the "Base A" inventories;
(6) S/L/T agency comments on the draft 2002 NEI;
(7) Revisions to CENRAP-sponsored inventories; and
(8) Comments from CENRAP's EI and Modeling Workgroups.

Table 3 provides a summary of the S/L/T agency data received for updating CENRAP's Base A inventories. Prior to using the data to update the Base A inventories, Pechan performed QA review of the inventories to identify (1) remaining QA issues that needed to be resolved through consultation with the agency and/or the EI and Modeling Workgroups, and (2) missing data that needed to be added to the inventories to support air quality modeling studies. As a result of the QA review, and after consulting with KS and MO, it was agreed that the point source inventory data they provided would not be used in the Base B point source inventory (see section II.B for additional details).

Table 3. Summary of S/L/T Agencies that Provided Data for Updating CENRAP's Inventories [1]

State/Local/Tribal Agency	Point	Area	Nonroad
AR	x[2]	x[3]	
Fond du Lac Band of the Minnesota Chippewa Tribe			
IA	x[4]		
KS	x[4,5]		
LA			
Leech Lake Band of Ojibwe Tribe	x[6]	x[6]	
MN	x[4]	x[3]	
MO	x[4,5]		
NE-State			
NE-Lincoln (Lancaster County)			
NE-Omaha (Douglas County)			
OK			
TX		x[4]	x[3]

1 An "x" identifies the sector for which a S/L/T agency provided data to revise the Base A inventory.
2 Agency provided inventory that completely replaced its Base A inventory data.
3 Agency provided comments on CENRAP's Base A inventory.
4 Agency provided comments on draft 2002 NEI that were used to update the Base A inventory.
5 Agency provided comments but comments not used per agreement with the agency.
6 Agency provided a new inventory not included in the Base A inventory.

After resolving the QA issues, the files were updated to revise or add data provided by the S/L/T agencies. In addition, the CENRAP's Base A NONROAD model inventory was revised to correct input data for the oxygen content of fuels and the SO_2 content of diesel fuel. Thus, the nonroad inventory for the NONROAD model categories was updated for all states that elected to use this inventory in the CENRAP inventory. Also, revisions were completed on all sectors to address comments from the EI and Modeling Workgroups.

The following sections B, C, and D provide the methods for updating CENRAP's 2002 Base A inventories for point, area, and nonroad sources, respectively. Each section discusses the QA review that was conducted on the S/L/T inventories to identify QA issues that were corrected to support air quality modeling. Then, each section discusses the augmentation procedures that were applied to fill in missing data. These procedures identify supplemental data that S/L/T agencies provided to add to or replace data in their inventories, the CENRAP-sponsored inventories that were added to the inventories as approved by the S/L/T agencies, and the 2002 NEI categories that S/L/T agencies requested to be added to their inventories. The augmentation procedures also explain how missing PM emissions were estimated and added to the inventories after incorporating inventory data supplied by S/L/T agencies, the CENRAP-sponsored inventory data, and data from the 2002 NEI.

Section E presents the data sources and methods for preparing the 2018 projection year inventory for EGUs. Section F documents the SMOKE and RPO data exchange protocol files prepared under this project.

B. Point Source Inventory Methods

1. Data Sources

For each S/L/T inventory that provided updates, Table 4 provides a summary of the pollutants included in each inventory, and compares the number of counties in the inventory to the number of counties in the 2002 preliminary NEI and in each S/L/T agency. The table also compares the number of facilities in the S/L/T inventory to the number of facilities in the 2002 preliminary NEI.

The inventories obtained from EPA are in Access 2000 databases in NIF 3.0. Each inventory was loaded into an Oracle database in NIF 3.0 to combine the inventories into a single data set. Then, after loading the inventories into Oracle in NIF 3.0, the following updates were performed on the consolidated data set, if necessary:

Table 4. Summary of Pollutants, Number of Counties, and Number of Facilities in Point Source Inventories

State/Local/ Tribal Agency	CO	NH_3	NO_x	PM-PRI	PM10-PRI	PM25-PRI	PM10-FIL	PM25-FIL	PM-CON	SO_2	VOC	Number of Counties in 2002 S/L/T Inventory Comments	Number of Counties in 2002 CENRAP Inventory[2]	Number of Counties in State	Number of Facilities in 2002 S/L/T Inventory Comments	Number of Facilities in 2002 CENRAP Inventory[2]
AR	x	x	x	x	x	x				x	x	57	70	75	231	1281
IA[1]										x		5	99	99	7	1871
KS[1]	x	x	x				x	x		x	x	4	105	105	4	5046
MN[1]	x	x	x		x	x		x		x	x	72	87	87	542	6095
Leech Lake Band of the Minnesota Ojibwe Tribe	x	x	x	x	x						x	-[3]	-[3]	-[3]	2	0

[1] State submitted comment records ("A" and "D" submittal flags). Therefore, entries will refer only to the "A" (Add) or "RA" (Revise Add) records. Note, ultimately KS inventory comments were not used to update the Base A inventory.

[2] Refers to the counties in the 2002 CENRAP modeling inventory which could include CENRAP-sponsored inventories for NH_3, fires, and confined animal feeding operations.

[3] NA = Not Applicable.

- Hazardous air pollutant (HAP) records were removed since the inventory will support regional haze, fine PM, and ozone modeling.

- Pollutant codes were corrected to make them NIF 3.0 compliant (e.g., update PMPRI pollutant code to PM-PRI). Additionally, other codes were identified for remediation on a case-by-case basis.

- The NIF 3.0 submittal flag field, when populated by an agency, provides the directions needed to determine how to revise the 2002 inventory. For this project, comment files obtained from EPA reflected comments on the draft NEI and not on CENRAP's 2002 inventory. Therefore, Pechan reviewed the submittal flag codes, compared the comment file to the CENRAP inventory, and consulted with the S/L/T agency to verify what records in the comment file were to be used to revise the CENRAP inventory. Pechan adjusted the submittal flags as necessary to document the records in the comment file that replaced records in CENRAP's 2002 inventory.

- Null values in the tribal code field were updated to '000' since this field is a part of the data key that defines records as unique in all eight NIF tables.

- The following NIF plus fields were added to the Transmittal (TR), Site (SI), Emission Unit (EU), Emission Release Point (ER), Emission Process (EP), Emission Period (PE), Emission (EM), and Control Equipment (CE) tables:

  - Data Source Codes:

Code	**Description**
S	State agency-supplied data.
L	Local agency-supplied data.
R	Tribal agency-supplied data.
P	Regional Planning Organization.
SC	S/L/T agency Corrected.
AUG-A	PM Augmentation: ad-hoc change.
AUG-C	PM Augmentation: standard augmentation method.
AUG-O	PM Augmentation: set PMxx-FIL = PMxx-PRI where for SCCs starting with 10 (external fuel combustion) and 20 (internal fuel combustion). Note: emission factors and particle-size data for estimating condensible emissions for fuel combustion SCCs starting with 30 were not available; therefore, condensible emissions were not estimated for these processes if an agency provided filterable and not primary emissions for these processes.
AUG-Z	PM Augmentation: automated fill-in of zero values where all PM for a particular process is zero.
GENPARENT	Data source where a parent record was system generated.

- Revision Date: This field indicates the month and year during which the last revision was made to a record. For the Base B inventory, for new or updated records, it is 0705.

- State Federal Information Processing Standard (FIPS): This field indicates the state FIPS code of the submittal.

- County FIPS: This field indicates the county FIPS code of the submittal.

- The following NIF plus fields were added to the EM table:

  - Emission Ton Value: This field indicates the values of the emissions in tons. This field was used to prepare summaries of emissions on a consistent emission unit basis.

  - Emission Type Period: This field indicates the period of the Emission Type – either ANNUAL or NONANNUAL. This field was used to prepare summaries of annual emissions.

  - CAP_HAP: This field identifies records for CAP versus records for HAPs. For the CENRAP inventory, the flag is CAP for all records.

  - Year: This field indicates the year of the data; for this inventory, it is 2002.

2. QA Review

QA review on the inventories was conducted in accordance with the QA procedures specified in the QAPP for this project (CENRAP, 2005b).

The following data elements were reviewed to identify QA issues:

- Emission Release Point (ERP) or Stack Coordinates;
- ERP (Stack) Parameters;
- PM Emissions Consistency and Completeness;
- Control Devices and Efficiencies;
- Start and End Dates; and
- Annual and Daily Emissions Comparison.

As appropriate, individual S/L/T agencies were contacted with QA questions in order to receive direction on corrections.

a. County and Facility Coverage

S/L/T agencies which submitted complete replacement inventories or replacement facility information (Arkansas, Leech Lake) were compared to their previous year’s submittal as

appropriate to determine if there is a significant change in county coverage, facility coverage, or emissions.

b. Pollutant Coverage

S/L/T agencies which submitted complete replacement inventories (Arkansas, Leech Lake) were reviewed for pollutant coverage and other potential issues. Arkansas' Base A inventory included emission data from the CENRAP-sponsored inventories for confined animal feeding operations and planned burning. The CENRAP-sponsored emissions data were merged with Arkansas' new inventory.

Arkansas, Minnesota, and Leech Lake include replacements and/or revisions to their PM data. On processes where the PM data were replaced or revised with new data, the PM augmentation routine was applied. The QA review of the PM data is discussed further in the following section, and the augmentation procedures are discussed in section II.B.4.

c. Particulate Matter (PM) Emissions Consistency and Completeness Review

The following consistency checks were performed at the EM table data key level (for annual emissions) to compare PM emissions:

- If a process was associated with a PM emission record, but was missing one or more of the following (as appropriate for the Source Classification Code [SCC] [i.e., condensible PM (PM-CON) is associated with fuel combustion only]): PM10-FIL, PM10-PRI, PM25-FIL, PM25-PRI, or PM-CON, the record was flagged for review.

- The following equations were used to determine consistency:

  PM10-FIL + PM-CON = PM10-PRI
  PM25-FIL + PM-CON = PM25-PRI
  PM-FIL + PM-CON = PM-PRI (as appropriate)

- The following comparisons were applied to determine consistency:

  PM10-PRI >= PM10-FIL
  PM25-PRI >= PM25-FIL
  PM10-PRI >= PM-CON
  PM25-PRI >= PM-CON
  PM10-FIL >= PM25-FIL
  PM10-PRI >= PM25-PRI
  PM-PRI >= PM10-PRI (as appropriate)
  PM-PRI >= PM25-PRI (as appropriate)
  PM-FIL >= PM10-FIL (as appropriate)
  PM-FIL >= PM25-FIL (as appropriate)

If the data failed one of these checks it was diagnosed as an error. If a S/L/T agency did not provide corrections to these errors, the errors were corrected/filled in according to the augmentation procedure discussed in section II.B.4.

d. Emission Release Point (ERP) Coordinate Review

Location coordinates for new point sources were evaluated using geographic information system (GIS) mapping to determine if the coordinates were within 0.5-kilometers of the boundary of the county in which the source was located. ERP records with coordinates located more than 0.5, 1, 2, 3, 5, 7, and 10 or more kilometers from their county boundary, and coordinates that mapped outside of their state boundary were identified. Arkansas' new point source inventory contained what appeared to be new coordinates not included in its Base A inventory. However, Arkansas indicated that the ERP information had not changed significantly since the original submittal was submitted for ERP coordinate review. Coordinates for the Leech Lake submittal were manually reviewed and it was verified that the coordinates fell within the tribal area boundaries.

e. ERP Parameter Review

The EPA's QA guidance for diagnosing ERP issues for the point source NEI (EPA, 2004b) was applied to identify QA issues in the S/L/T point source inventories. The QA guidance involved diagnosing the correct assignment of the ERP type (i.e., stack or fugitive), parameters with zero values, parameters not within the range of values specified in the EPA's QA procedures, and consistency checks (i.e., comparing calculated values against expected values). In many cases errors were due to defaulted zeros, and submitting agencies were requested to provide the value. In other cases, out-of-range errors were caused by unit conversion issues (e.g., stack parameters were in ft, ft/sec, cu ft/sec or degrees Fahrenheit). The data were corrected or filled in according to the ERP parameter augmentation procedure discussed in section II.B.4.

f. Control Device Type and Control Efficiency Data Review

The CE codes in the "Primary Device Type Code" and "Secondary Device Type Code" fields were reviewed to identify invalid codes (i.e., codes that did not exist in the NIF 3.0 reference table) and missing codes (e.g., records with a null or uncontrolled code of 000 but with control efficiency data).

QA review of control efficiency data involved diagnosis of two types of errors. First, records were reviewed to identify control efficiency values that were reported as a decimal rather than as a percent value. Records with control efficiencies with decimal values were flagged as a potential error (although not necessarily an error, since the real control efficiency may be less than 1 percent).

The second check identified records where 100 percent control was reported in the CE table, but the emissions in the EM table were greater than zero and the rule effectiveness value in the EM table was null, zero, or 100 percent (implying 100 percent control of emissions). Because many agencies did not populate the rule effectiveness field or a default value of zero was assigned, records with null or zero rule effectiveness values were included where the CE was 100 percent

and emissions were greater than zero. All new data submitted for updating CENRAP's point source inventory passed these QA checks.

g. Start and End Date Checks

QA review was conducted to identify start date and end date values in the PE and EM tables to confirm consistency with the inventory year in the transmittal table, and to confirm that the end date reported is greater than the start date reported. This check did not identify any QA issues with the data used to update the Base A inventory.

h. Annual and Daily Emissions Comparison

The following QA checks were conducted to identify potential errors associated with the incorrect reporting of daily and/or annual emissions:

- Multiple records coded at the process level as emission type 30, but with different start and end dates. While not a true duplicate, this may indicate an error or an inclusion of both annual and seasonal values. Only one record can be identified as the "ANNUAL" record.

- Multiple records coded at the process level (or SCC, in the case of area) as a daily emission type (27, 29, etc.) but with different start and end dates. While not a true duplicate, this may indicate an error or just an inclusion of additional types of daily emissions.

- Multiple records coded at the process level (or SCC, in the case of area) with the same start and end date, but different emission types. While not a true duplicate, this may indicate an error or just an inclusion of additional types of daily emissions.

All new data submitted for updating CENRAP's point source inventory passed these QA checks.

3. Responses from S/L/T Agencies

The S/L/T agencies provided responses to questions about their data. When necessary, QA issues were summarized in Excel spreadsheets and sent to the agencies and the EI and Modeling Workgroups for review. The agencies or the Workgroups then provided direction for correcting the issues either by telephone or by e-mail.

4. Gap Filling and Augmentation

The following discusses the augmentation procedures that were used to fill in missing data that were not supplied by the S/L/T agencies.

a. PM Augmentation

Pechan implemented procedures to estimate missing pollutant data from data provided by the S/L/T agencies in order to develop a complete set of PM10-PRI and PM25-PRI emissions to support air quality modeling.

The PM augmentation process gap-filled missing PM pollutant complements. For example, if a S/L/T agency provided only PM10-PRI pollutants the PM augmentation process filled in the PM25-PRI pollutants. The steps in the PM augmentation process were as follows:

- Initial QA and remediation of S/L/T provided PM pollutants;
- Development of PM factor ratios based on factors from the Factor Information and REtrieval (FIRE) Data System (Version 6.2) and the PM Calculator (EPA, 2003; EPA, 2004c);
- Implementation of the ratios; and
- Presentation of PM augmentation results to S/L/T agencies for review and comment.

Note: An Access database accompanies this documentation - *Reference Tables for PM Augmentation*. This database contains the SCC Control Device Ratio table, the Emission Factors table and Emission Factors Crosstab table discussed in Step 2. The PM Calculator ratio table can be provided upon request – it contains all possible combinations for SCC and Control Device types that are available in the PM Calculator.

These steps are further detailed below.

1. Initial QA and Remediation of PM Pollutants

S/L/T agencies were initially presented with files that detailed potential inconsistencies and missing information in their PM pollutant inventory. Inconsistencies in PM pollutants include the following:

- PM-PRI less than PM10-PRI, PM25-PRI, PM10-FIL, PM25-FIL, or PM-CON
- PM-FIL less than PM10-FIL, PM25-FIL
- PM10-PRI less than PM25-PRI, PM10-FIL, PM25-FIL or PM-CON
- PM10-FIL less than PM25-FIL
- PM25-PRI less than PM25-FIL or PM-CON
- The sum of PM10-FIL and PM-CON not equal to PM10-PRI
- The sum of PM25-FIL and PM-CON not equal to PM25-PRI

Potential missing information was summarized in a table which detailed the variety of cases provided by the S/L/T agency. For example, a S/L/T agency might have provided PM10-FIL and PM25-FIL for some processes, but for other processes only PM10-FIL was provided.

S/L/T agencies were asked to review this information and provide corrections where possible. In general, corrections (or general directions) were provided in the case of the potential inconsistency issues. An example of a general direction provided by a S/L/T agency was to

remove PM25-FIL where greater than PM10-FIL because the PM10-FIL was (in their particular case) known to be more reliable. In other cases, the agency-provided specific process level pollutant corrections. In general, if specific direction was not provided by the agency, priority was given to the PM_{10} number.

2. Development of PM Factor Ratio

The primary deliverable of this step of the process was the development of a table keyed by SCC, primary control device, and secondary control device. This table is called the SCC Control Device Ratios table. The table structure is shown in Table 5 which follows the discussion below.

This table was filled according to the following steps:

- Ratios (both condensible and noncondensible) were added from FIRE for SCCs starting with 10* (external fuel combustion) and 20* (internal fuel combustion) where there was a direct match between the provided SCC, and primary and secondary control devices.
- Ratios (non-condensable) were added from the PM Calculator for SCCs starting with 10* and 20* where there was not a direct match between the provided SCC, and primary and secondary control devices. Condensible ratios were added from the PM Calculator based on the uncontrolled SCC for these SCCs. In some cases, it was necessary to map the SCC and control devices to the PM calculator to find a match for the noncondensible ratios. In some cases, it was necessary to map the SCC to FIRE to find a match for condensible ratios.
- For natural gas, process gas and liquefied petroleum gas SCCs starting with 10* and 20*, it was assumed (based on FIRE emission factors trend) that the PM-PRI/PM10-PRI/PM25-PRI ratio was equal to 1. It was also assumed that the PM-FIL/PM10-FIL /PM25- FIL was equal to 1. Condensible ratios were calculated from uncontrolled FIRE emission factors based for these SCCs. In some cases it was necessary to map the SCC to FIRE to find a match for condensible ratios.
- Ratios for SCCs not like 10* and 20* were obtained from the PM Calculator. It was assumed that the condensible component was zero.

Accompanying this document is a database containing the SCC Control Device Ratios table. Additionally, the Emission Factors and Emission Factors Crosstab table (which are derived from FIRE) are provided. The Emission Factors Crosstab table contains the ratios developed from the Emission Factors table. The Emission Factors table contains detailed information on the emission factors used to develop the ratios.

Note: Ratios from the PM calculator were developed using a standard input of 100 TONS of uncontrolled PM-FIL emissions.

Table 5. Description of the Field Names and Descriptions for the SCC Ratio Table

Field Name	Field Description
PM Calculator	A “Yes” in this field indicates that at least some of the information was retrieved from the PM Calculator
FIRE	A “Yes” in this field indicates that at least some of the information was retrieved from the Emission Factors table. A “Condensible Ratios” in this field indicates that the condensible ratios factors were retrieved from this table.
Other	A field to indicate other sources as necessary.
SCC	Source category code from the S/L/T agency-provided data.
SCC_DESC	Description of source category code from the S/L/T agency-provided data.
maptoSCC	This field equals SCC unless the SCC provided was not found in the appropriate source table. In that case, the SCC was mapped using the closest available appropriate mapping choice.
maptoSCC_DESC	Description of the maptoSCC.
mapSCCNote	Any notes related to the mapping of the SCC. A “Yes” in this field indicates that the SCC was mapped.
PD	Primary device type from the S/L/T agency provided data.
PD_DESC	Description of the primary device (PD).
maptoPD	This field equals PD unless the PD provided was not found in the appropriate source table. In that case, the PD was mapped using the closest available appropriate mapping choice.
maptoPD_DESC	Description of the maptoPD.
mapPDNote	Any notes related to the mapping of the PD. A “Yes” in this field indicates that the PD was mapped.
SD	Secondary device type from the S/L/T agency provided data.
SD_DESC	Description of the secondary device (SD).
maptoSD	This field equals SD unless the SD provided was not found in the appropriate source table. In that case, the SD was mapped using the closest available appropriate mapping choice.
maptoSD_DESC	Description of the maptoSD.
mapSDNote	Any notes related to the mapping of the SD. A “Yes” in this field indicates that the SD was mapped.
PM-FIL/PM10-FIL	This field and the following are ratios calculated from emission factors found either in FIRE or the PM calculator.
PM-FIL/PM25-FIL	This field and the following are ratios calculated from emission factors found either in FIRE or the PM calculator.
PM-FIL/PM-PRI	This field and the following are ratios calculated from emission factors found either in FIRE or the PM calculator.
PM-PRI/PM10-PRI	This field and the following are ratios calculated from emission factors found either in FIRE or the PM calculator.
PM-PRI/PM25-PRI	This field and the following are ratios calculated from emission factors found either in FIRE or the PM calculator.
PM10-FIL/PM25-FIL	This field and the following are ratios calculated from emission factors found either in FIRE or the PM calculator.
PM10-PRI/PM25-PRI	This field and the following are ratios calculated from emission factors found either in FIRE or the PM calculator.
PM-CON/PM10-FIL	Condensible ratios were calculate from FIRE if available for 10* and 20* SCCs. If condensible ratios were not found in FIRE for 10* and 20* these ratios were set to zero.
PM-CON/PM10-PRI	Condensible ratios were calculate from FIRE if available for 10* and 20* SCCs. If condensible ratios were not found in FIRE for 10* and 20* these ratios were set to zero.
PM-CON/PM25-FIL	Condensible ratios were calculate from FIRE if available for 10* and 20* SCCs. If condensible ratios were not found in FIRE for 10* and 20* these ratios were set to zero.
PM-CON/PM25-PRI	Condensible ratios were calculate from FIRE if available for 10* and 20* SCCs. If condensible ratios were not found in FIRE for 10* and 20* these ratios were set to zero.
PM-CON/PM-FIL	Condensible ratios were calculate from FIRE if available for 10* and 20* SCCs. If condensible ratios were not found in FIRE for 10* and 20* these ratios were set to zero.
PM-CON/PM-PRI	Condensible ratios were calculate from FIRE if available for 10* and 20* SCCs. If condensible ratios were not found in FIRE for 10* and 20* these ratios were set to zero.
RPO Specific Note	Indicates SCC and control device combinations are in the RPO inventory.
Additional Notes	Any notes regarding assumptions about ratios.

3. *Implementation of the QA Ratios*

In order to calculate the additional PM pollutants based on the SCC Control Device ratio table developed in the above step, a crosstab table was created from the EM table based on the following fields:

- State FIPS
- County FIPS
- Tribal Code
- Emission Unit identification (ID)
- Process ID
- Start Date
- End Date
- Emission Type
- SCC
- Primary Device Type
- Secondary Device Type

The primary and secondary device type fields were added based on information from the CE table. If control equipment information was not available these fields were defaulted to 000 ("UNCONTROLLED"). In the few cases where there was a conflict between the control devices reported for the same process for PM pollutants (for example, a PM10-PRI is listed as controlled, but PM-PRI did not have control information), the control device type was selected based on the controlled pollutant.

In addition to the fields listed above, the crosstab included the PM emission amounts for the particular process and a field that indicated whether those emissions existed in the inventory. These fields are as follows:

- PM_PRI
- PM_FIL
- PM10_PRI
- PM10_FIL
- PM25_PRI
- PM25_FIL
- PM_CON
- PM_PRI_EXISTS
- PM_FIL_EXISTS
- PM10_PRI_EXISTS
- PM10_FIL_EXISTS
- PM25_PRI_EXISTS
- PM25_FIL_EXISTS
- PM_CON_EXISTS

The emission values are in the PM_PRI, PM_FIL, PM10_PRI, PM10_FIL, PM25_PRI, PM25_FIL, PM_CON fields. The _EXISTS field indicates whether the pollutant was provided by the S/L/T agency. A zero indicates that the pollutant was not provided; a number greater than zero (usually one) indicates that it was provided by the S/L/T agency.

Prior to the development of this crosstab, the EM table was filled in as much as possible using basic assumptions. For example, if the S/L/T agency provided emissions that were equal to zero for PMs for a particular process, it was assumed that all PMs for that process were zero and they were filled in accordingly. Since the assumption was that for non 10* and 20* SCCs, the condensible value was zero – that would lead to PM10-FIL = PM10-PRI and PM25-FIL = PM25-PRI and PM-FIL = PM-PRI. Given that assumption, values for these pollutants were also filled in. After this data insertion, a subset of the crosstab was created. This subset only contained processes that required additional augmentation. The SCC control device type ratio table described in step 2 was based on only those SCC and control device types that required augmentation.

The next step was to fill in the missing information in this crosstab using the information found in the SCC Control Device Ratio table.

In calculating PM complement pollutants, priority was given to calculating –PRI and –CON pollutants. FIL pollutants were only calculated if necessary to calculate other pollutants or if it was a by-product of this calculation.

In augmenting the PM pollutants the non 10* and 20* SCCs were augmented first, with order given to augmenting based on PM_{10} where available, PM_{25} where available, and then PM .

Augmenting the PM pollutants for the 10* and 20* SCCs is more complicated, but the basic approach was to augment based on PM_{10} (FIL or PRI) where available, $PM_{2.5}$ (FIL or PRI) where available, and then PM (FIL or PRI) if PM_{10} or $PM_{2.5}$ variations were not available. Where both PM_{10} (FIL or PRI) and $PM_{2.5}$ (FIL or PRI) variations were both available, the calculation for PM-CON was generally driven from the PM_{10} number and the complements as necessary were back calculated. Where a –PRI emission factor ratio was required and was not available the –FIL emission factor ratio was used.

After calculations, the data was QA checked to ensure that the calculations resulted in consistent values for the PM complement. On a few occasions, the mix of ratio value and the pollutants and values provided by the S/L/T agency resulted in negative values when –FIL was back-calculated. In this case the negative –FIL value was set to zero and the –PRI value was readjusted.

The resultant PM table has the format described in Table 6.

Note: **There are some high condensible ratios that were calculated for some SCC device type combinations. In most cases these high condensible ratios were the result of the back calculation of PM-CON from PM10-PRI or PM25-PRI records. Since the state had**

already provided the PMxx-PRI records, these PM-CON values were not added to the inventory.

Table 6. Description of the Field Names and Descriptions for the Resulting PM Augmentation Table

Field Name	Field Description
Augment	A "Yes" in this field indicates that the process PM was augmented.
Condensible Note	If condensible information was added this field will note that.
STATE_FIPS	State FIPS
COUNTY_FIPS	County FIPS
STATE_FACILITY_IDENTIFIER	Site ID
EMISSION_UNIT_ID	Emission Unit
PROCESS_ID	Process
START_DATE	Start Date
END_DATE	End Date
EMISSION_TYPE	Emission type
SCC	Source Category Code
SCC_DESC	SCC description
PRIMARY_DEVICE_TYPE	Primary Device Type
PRIMARY_DEVICE_TYPE_DESC	PDT description
SECONDARY_DEVICE_TYPE	Secondary Device Type
SECONDARY_DEVICE_TYPE_DESC	SDT description
EMISSION_TYPE_PERIOD	Emission Type Period
EMISSION_RELEASE_POINT_ID	Emission Release Point ID
FACILITY_NAME	Facility Name
ORIS_FACILITY_CODE	ORIS facility Code
SIC_PRIMARY	SIC
ACTUAL_THROUGHPUT	Actual Throughput
THROUGHPUT_UNIT_NUMERATOR	Throughput Unit Numerator
PM_PRI	Emission ton value for PM-PRI
PM_FIL	Emission ton value for PM-FIL
PM10_PRI	Emission ton value for PM10-PRI
PM25_PRI	Emission ton value for PM25-PRI
PM10_FIL	Emission ton value for PM10-FIL
PM25_FIL	Emission ton value for PM25-FIL
PM_CON	Emission ton value for PM-CON
PM_PRI_EXISTS	0 if the S/L/T agency did not provide, > 0 if S/L/T agency did provide
PM_FIL_EXISTS	0 if the S/L/T agency did not provide, > 0 if S/L/T agency did provide
PM10_PRI_EXISTS	0 if the S/L/T agency did not provide, > 0 if S/L/T agency did provide
PM25_PRI_EXISTS	0 if the S/L/T agency did not provide, > 0 if S/L/T agency did provide
PM10_FIL_EXISTS	0 if the S/L/T agency did not provide, > 0 if S/L/T agency did provide
PM25_FIL_EXISTS	0 if the S/L/T agency did not provide, > 0 if S/L/T agency did provide
PM_CON_EXISTS	0 if the S/L/T agency did not provide, > 0 if S/L/T agency did provide
RECORD_COUNT	0 if the S/L/T agency did not provide, > 0 if S/L/T agency did provide
System Update Note	This field contains system codes related to the update queries used to calculate the record.

The data source code field is used to identify records that are added to the inventory to complete the set of PM10-PRI and PM25-PRI emissions needed to support modeling.

b. ERP Coordinates

If a S/L/T agency did not provide corrections for ERP coordinates that map more than 5 km outside of the county boundary, or provide coordinates for ERP records that did not have any coordinates in the S/L/T inventory, the following procedures were applied to replace the coordinates:

- Coordinates for other ERPs at the same facility, if available, that map within the county;
- Coordinates for the centroid of the zip code for a facility if a valid zip code is provided or can be obtained from the agency if it is not valid; or
- County centroid coordinates.

The zip code was taken from the SI NIF 3.0 table. The zip code was compared to a reference table of valid zip codes to verify that it is an active zip code and exists in the state and county reported in the inventory. For example, a zip code may be invalid if it is for the mailing address or address of a facility's parent company rather than the address of the facility's location. If a valid zip code for a facility was not identified, Pechan used the centroid for the facility's county as a last resort.

c. ERP Parameters

If valid ERP parameters were not provided by the S/L/T agency, Pechan applied the ERP augmentation procedures for the 2002 point source NEI (EPA, 2004b). It has been determined that the augmentation procedures in this document regarding SCC-specific ERP types and temperatures are difficult to resolve. When this situation occurs, preference was given to the state-supplied ERP type and SCC. For example, the procedures do not account for cases where an emission unit has two processes with one defined as a stack source and the other as a fugitive source. Therefore, the S/L/T-supplied ERP type was used when this situation occurred.

d. Control Device Type and Control Efficiency Data

If a S/L/T agency did provide valid control device type codes to replace invalid codes identified in the inventory, Pechan changed the valid NIF 3.0 code of 099 for miscellaneous control devices. In the case of modeled data where no control device information was provided, the records were left unchanged.

Pechan expected that control equipment data issues would be resolved through consultation with the S/LT Agencies. Default augmentation procedures were developed and applied to resolve control efficiency issues. In the event that control efficiency issues were not resolved, Pechan documented the QA issues in the final report.

5. Revisions to Address Comments

The following items were revised per S/L/T agency instructions:

a. Arkansas

Arkansas sent a complete replacement inventory. Arkansas confirmed that they revised the SCCs and emissions in this new inventory. Therefore, the previous Base A inventory was used as a guide for correcting ER coordinates and stacks and other QA issues.

County 777 information was removed from the entire inventory (4 facilities with 34 emission records).

CE

It was noted by Arkansas that they had not sent any CE records. They confirmed this as intentional.

EM

Removed PM-PRI and PM-FIL with emission numeric values of 0 (2,437 records) and 8 PM10-FIL/PRI records where the remaining PMxx-FIL/PRI information was non-zero.

Updated emission calculation method code from 4 to 04 (1,706 records).

Material codes of "0" were nulled out (44 records).

Material IO codes of "U" were nulled out (44 records).

Nulled out the invalid factor unit denominator value of "UNK", or nulled out the factor unit denominator value if the factor unit numerator was null (44 records).

Where PM25-PRI values were greater than PM10-PRI values, the PM25-PRI values were set equal to PM10-PRI values per instruction from the state.

Note: The NH_3 emissions in Arkansas' new inventory decreased considerably from the emissions in the Base A inventory. A comparison of the emissions was provided to Arkansas for review and confirmation that the revised emissions are correct.

PE

Material codes of "0" were nulled out (6 records).

Material IO codes of "U" were nulled out (6 records).

Nulled out throughput unit numerator where noted as "UNK" (6 records).

EP

The Arkansas inventory contained six inactive SCCs (i.e., SCCs in EPA's February 2004 master list that are identified as no longer used by EPA) that were changed to active SCCs as follows:

- 28888802 was replaced by 28888801
- 30800197 was replaced by 30800199
- 30703096 was replaced by 3070399
- 30703098 was replaced by 3070399
- 30699998 was replaced by 30699999
- 30700798 was replaced by 30700799

Updated one EP record to reset its operating percentages for the 4 seasons from all 24s to all 25s in order to make the sum of activity consistent.

ER

Where EP was parentless, ER records were added to the inventory. The ERP type was set to "01" if total stack emissions for all pollutants combined was less than or equal to 100 tons per year, or to "02" if total stack emissions for all pollutants combined was more than 100 tons per year.

21 invalid ER types were updated based on the Base A inventory.

Updated 107 of Arkansas coordinates based on Base A inventory.

Stack augmentation and coordinate augmentation was implemented on any remaining missing or invalid values.

EU

One emission unit record was generated in order to maintain referential integrity.

SI

Two site records were generated in order to maintain referential integrity.

TR

The affiliation type "report_certifier" was changed to "Report Certifier".

b. Iowa

Iowa provided additions and revisions to their SO_2 emissions. These revisions were applied to their submittal.

EM

Emission revisions were made to records where the data keys in the comments matched those in the inventory. Emission records were added to the Base B inventory where there was no data key match. In order to maintain referential integrity, records in the comment file were added to the ER, EU, EP, and PE tables. In addition, a correction was made to the start and end dates to ensure that they all started with 2002, in some cases, 2003 was used.

c. Kansas

Kansas provided comments to the EPA; however, after an initial incorporation of emission comments into the inventory – it was determined through state review that the comments did not apply to the CENRAP inventory. These emissions were restored to their original values. Essentially, the Kansas inventory remained unchanged.

d. Minnesota

Minnesota submitted new information for municipal airport emissions as well as revisions to their PM data.

ER

When inserting the new municipal airport emissions, 236 fugitive records were defaulted to the fugitive defaults. Eight records noted as stacks were defaulted to stack defaults. Coordinates were compared manually either to the previous Minnesota submittal which had been QA checked or manually compared to known county boundaries.

EM

When incorporating the new municipal airport information, it was determined that there were 13 duplicate records and one inconsistent ER-EU combination for NH_3. The new information submitted was selected over the previous information.

Minnesota included updates to their PM information. Where the PM values were new, they were added to the inventory (after removing previously augmented data). Where the PM values were revisions, the records were revised (after removing previously augmented data). When the PM QA check indicated that there were significant discrepancies between the relative values of PM10-PRI and PM25-PRI, it was determined through consultation with the state there was a problem in the export program that the state used to create the NIF 3.0 text file. Essentially, it was truncating the exponential part of the emission numeric value in the file. Minnesota provided a corrected file. This corrected file was used to update the PM25-FIL/PRI values. After these values were incorporated, there were still several comparative problems. Upon review, it was determined that a number of these comparative problems were due to rounding –

essentially comparing numbers in this fashion - PM10-PRI = 0.01999 and PM25-PRI = 0.02. The program would flag an error, even though it was a result of rounding. In these cases, the values were rounded appropriately. For 55 records, the PM25-PRI values were set to the calculated value in order to resolve this type of issue. After resolving these values, the PM augmentation procedure was run.

Wildfires and Agricultural Field Burning

For the Base A modeling effort, the Midwest RPO's point source inventory for wildfires (SCC 2810001000) and agricultural field burning (SCC 2801500000) was to be used for Minnesota. The point source inventory was included in the NIF 3.0 file for Minnesota to support development of emissions summaries (the Midwest RPO provided the inventory in point source SMOKE input format). However, it was learned that the Midwest RPO point source inventory was not being used for modeling so the 2002 point source wildfire and agricultural field burning emissions data were removed from the Base B point source inventory and restored to the Base B area source inventory.

e. Leech Lake

Leech Lake provided a new inventory that was not included in the Base A inventory.

ER

Leech Lake did not provide stack information for a fugitive ERP. This was defaulted to the stated default fugitive ERP values.

Leech Lake did not provide exit velocity and exit flow information for two ERPs. These were defaulted according to the methods document.

EM

Leech Lake did not provide PM25-PRI emissions. For the point source SCCs, PM25-PRI emissions were estimated based on the PM augmentation methods. For the single area source SCC for prescribed burning, the PM25-PRI emissions were estimated by dividing the PM10-PRI emissions by a ratio of 1.14. This ratio is the lower of two values (1.18 and 1.14) most commonly used by the Midwest RPOduring the development of the Minnesota prescribed burning inventory.

An examination of duplicates between tribal information and state information yielded one potential site duplicate – the Cloquet County municipal airport is listed in both the Minnesota (27017-000-27017XCOQ) and Leech Lake (00000-407- 05) inventories. The airport emissions in the two inventories are significantly different (29 tons of CO for Minnesota and .04 tons of CO for the tribe – the largest emission set) and there was insufficient information to determine if the emissions were duplicated when combined into the Base B inventory. The prescribed burning emissions for Leech Lake were also compared to the Minnesota prescribed burning inventory, and it was determined that there were no common ERP coordinates or other

information to indicate duplication of data. Thus, the airport emissions and prescribed burning emissions in Leech Lake's inventory were included in the Base B point source inventory.

f. Missouri

Missouri provided a complete replacement inventory; however, upon further discussion and agreement with Missouri, the replacement inventory was not use to update the Base A inventory.

g. All CENRAP S/L/T agencies - Office of Regulatory Information Systems (ORIS) and ORIS Boiler ID Updates

The ORIS identifiers in the SI and EU table were updated based on the crosswalk entitled CENRAPxwalk051005.mdb with modifications made for some emission unit identifier changes made by Arkansas. The revised crosswalk including the Arkansas changes was delivered to CENRAP on August 11, 2005.

h. Stack Parameter updates per CENRAP instructions

In addition to individual state submittals of data, stack parameter corrections were supplied to Pechan through CENRAP. These stack parameter comments affected 20 ERP records (4 in Iowa, 6 in Kansas, 5 in Louisiana, and 5 in Oklahoma) in one set of comments, and 15 records for Arkansas in another set of comments. There were some initial QA issues with the flow rate calculation; however, these issues were resolved by CENRAP and the revised comments were used to update the Base A inventory.

6. QA Review of Final Inventory

Final QA checks were run on the revised point source inventory data set to ensure that all corrections provided by the S/L/T agencies were incorporated into the Base B inventory and that there were no remaining QA issues that could be addressed during the duration of the project. After exporting the inventory in Oracle to an Access database in NIF 3.0, the EPA QA program was run on the Access database and the QA output was reviewed to verify that all QA issues that could be addressed were resolved (EPA, 2004a)

This file accompanies this documentation with the specific details included. The following summarizes the remaining QA issues that could not be addressed during the duration of this project (listed by table):

<u>CE</u>

Primary device type codes are null for the confined animal feeding operations and planned burning (forest and rangeland). The data originates from the CENRAP-sponsored inventories for these categories. Missouri also has null primary device types for the majority of the CE records it provided for NH_3 emissions.

<u>EM</u>

The EPA QA program indicated that some emissions were outside the expected range. While this is a guideline and not a specific error, this listing could be reviewed for high values.

PE

There are a few (32) records with the units M2 and MASS that were not yet in the EPA QA program units reference table.

There are a few (8) remaining records with operating times outside the EPA QA program ranges.

EP

There are a few (9) remaining records with operating parameters and seasonal sums outside the expected range.

The SCC 30202000 has not yet been added to the EPA QA program SCC reference table.

ER

A significant number of records are missing the supplementary coordinate reference information (Horizontal data measure, horizontal data accuracy, horizontal collection method code).

Several records indicate coordinates outside of county boundaries – the reasons why this may occur were explained in the coordinate augmentation section earlier in this document.

Several records also indicate stack parameters outside of ranges expected by the EPA QA program. This is due either to the S/L/T agency specifically requesting not to change the values or to default values in the EPA table which fall outside of the EPA QA program ranges.

EU

Standard industrial classification (SIC) code 3041 is not in the SIC code table.

SI

The inventories (particularly the NH_3 inventory for confined animal feeding operations) did not provide zip code information with the site data. This accounts for a tremendous number of the invalid zip code errors found when running the EPA QA program. There are other records with zip code errors in addition to these; however, these inventories are the source of the majority of these errors.

NAICs codes are missing or invalid on some records (470), primarily in Nebraska and Oklahoma which did not provide comments during this time. The location address is missing for some records in Minnesota and Nebraska.

TR

Some records are missing the transaction creation date information.

C. Area Source Inventory Methods

1. Data Sources

The states of AR, TX, and MN provided comments for updating the Base A inventory. AR and MN provided comments on the Base A inventory, and TX provided comments on the draft 2002 nonpoint NEI that were applied to update the Base A inventory. The Leech Lake Band of Ojibwe Tribe provided a new area source inventory. In addition, the EI and Modeling Workgroups provided several comments resulting in revisions to the area source inventory. Documentation of the revisions made to the Base A inventory are provided in section II.C.5.

The data files that the states provided for updating the Base A inventory were loaded into Oracle in NIF 3.0 into one data set. Then, the following updates were performed on the consolidated data set, if necessary:

- HAP records were removed since the inventory will support regional haze, fine PM, and ozone modeling.

- Pollutant codes were corrected to make them NIF 3.0 compliant (e.g., update PMPRI pollutant code to PM-PRI). Additionally, other codes were identified for remediation on a case-by-case basis.

- The NIF 3.0 submittal flag field, when populated by an agency, provides the directions needed to determine how to revise the 2002 inventory. TX's comment file reflected comments on the draft NEI and not on CENRAP's 2002 inventory. Therefore, Pechan reviewed the submittal flag codes, compared the comment file to the CENRAP inventory, and consulted with TX to verify what records in the comment file were to be used to revise the CENRAP inventory. Pechan adjusted the submittal flags as necessary to document the records in the comment file that replaced records in CENRAP's 2002 inventory.

- Null values in the tribal code field were updated to '000' since this field is a part of the data key that defines records as unique in all five NIF tables.

The following NIF plus fields were added to the EP, PE, EM, and CE tables:

- Data Source Codes:

For the area and nonroad inventory data, the data source codes were based on the following 9-character format:

[Data Origin]-[Year]-[Grown/Not Grown/Carried Forward]-[PM Augmentation Code]

Code	Field Length
Data Origin	1
Year	3 (including leading hyphen)
Grown/Not Grown/Carried Forward	2 (including leading hyphen)
PM Augmentation	3 (including leading hyphen)

Data Origin Codes

Code	Description
S	State agency-supplied data
L	Local agency-supplied data
R	Tribal agency-supplied data
P	Regional Planning Organization-generated data
E	EPA/Emission Factor and Inventory Group (EFIG)-generated data

Year Codes

Year for which data were supplied (e.g., Year = -02 for 2002), or from which prior year data were taken (e.g., Year = -99 for 1999; -01=2001).

Grown/Carried Forward/Not Grown Codes

Code	Description
-G	Used when emissions in a pre-2002 inventory were grown to represent 2002 emissions.
-F	Used when emissions in a pre-2002 inventory were carried forward and included in the 2002 inventory without adjustment for growth.
-X	Used when the emissions were not grown or were not carried forward. For example, X was used when emissions were calculated for the 2002 inventory using 2002 activity, or when data were replaced with 2002 S/L/T data.

PM Augmentation Codes

-PA	PM Augmented Emissions: Record for PM_{10}/$PM_{2.5}$ emissions that were updated or added using ad-hoc updates.
-PC	PM Augmented Emissions: Record added for PM_{10}/$PM_{2.5}$ emissions estimated using the PM Calculator.
-PR	PM Augmented Emissions: Record added for PM_{10}/$PM_{2.5}$ emissions estimated using ratios of PM_{10}-to-PM or $PM_{2.5}$-to-PM_{10}. If PM_{10} and $PM_{2.5}$ emissions were equal and one of the pollutants was assigned this code, the ratio was assumed to be 1.
-VR	Missing pollutant estimated by multiplying the ratio of the missing pollutant emission factor to the VOC emission factor by the VOC emissions supplied by the S/L/T agency. This method was applied to estimate missing pollutant emissions in the 2002 NEI only. Records with this data source code in

CENRAP's Base B inventory indicate that the data were copied from the NEI as directed by CENRAP agency comments.

-NR Missing pollutant estimated by multiplying the ratio of the missing pollutant emission factor to the NO_x emission factor by the NO_x emissions supplied by the S/L/T agency. This method was applied to estimate missing pollutant emissions in the 2002 NEI only. Records with this data source code in CENRAP's Base B inventory indicate that the data were copied from the NEI as directed by CENRAP agency comments.

2 QA Review

QA review was conducted on the S/L/T area source inventories in accordance with the QA procedures specified in the QAPP for this project (CENRAP, 2005b). The following discusses the QA checks that were completed during preparation of the Base B inventory.

a. County and SCC Coverage

The county coverage in the state inventories appeared to be reasonable for all states. The SCC coverage was difficult to evaluate simply by showing a count of the number of SCCs by state. The EI and Modeling Workgroups reviewed summaries comparing the Base B to the Base A inventory and provided comments that are explained under section II.C.5.

b. Pollutant Coverage

The pollutant coverage in the S/L/T inventories was complete for all pollutants except for PM_{10} and $PM_{2.5}$. Diagnosis and resolution of PM_{10} and $PM_{2.5}$ pollutant emissions is discussed later in section II.C.5.

d. Additional QA for the CENRAP Area Source Inventory

The following explains additional QA that was performed for the CENRAP inventory. The following data elements were reviewed to identify QA issues:

- Range Errors;
- PM Emissions Consistency and Completeness;
- Control Device Codes and Control Efficiency Values;
- Start and End Dates;
- Annual and Daily Emissions Comparison; and
- Comparison of Base B to the Base A inventory.

As appropriate, individual S/L/T agencies were contacted with QA questions in order to receive direction on corrections.

Range Errors

The EPA's QA program was run on MN's and TX's comment files. The range errors identified by the QA program were deemed acceptable. Note that according to EPA, the ranges to which values in inventories are compared represent "normal" ranges that are based on percentiles from previous inventories. The range values are conservative in that EPA wants to identify suspicious values even though the values may be real (Thompson, 2002).

PM Emissions Consistency and Completeness Review

The following consistency checks were performed at the EM table data key level (for annual emissions) to compare PM emissions:

- If an SCC was associated with a PM emission record, but was missing one or more of the following (as appropriate for the SCC [i.e., PM-CON is associated with fuel combustion only]): PM10-FIL, PM10-PRI, PM25-FIL, PM25-PRI, or PM-CON, the record was flagged for review.

- The following equations were used to determine consistency:

  PM10-FIL + PM-CON = PM10-PRI
  PM25-FIL + PM-CON = PM25-PRI

- The following comparisons were made to determine consistency:

  PM10-PRI >= PM10-FIL
  PM25-PRI >= PM25-FIL
  PM10-PRI >= PM-CON
  PM25-PRI >= PM-CON
  PM10-FIL >= PM25-FIL
  PM10-PRI >= PM25-PRI

If the data failed one of these checks it was diagnosed as an error. If a S/L/T agency did not provide corrections to these errors, the errors were corrected/filled according to an augmentation procedure explained in sections II.C.4 and II.C.5.

For information purposes, all PM-PRI and PM-FIL records were flagged to indicate that these pollutants were included instead of, or in addition to, the standard PM_{10}, $PM_{2.5}$, and PM-CON pollutants.

TX's area source inventory had many records that did not meet the PM consistency and completeness. Many of the errors occurred as a result of TX providing revisions on filterable emissions and not revising the primary emissions. Also, TX added daily filterable emissions for many categories but did not provide daily primary emissions. TX was consulted on how to resolve the PM issues and TX provided directions on how to correct the issues.

Control Device Type and Control Efficiency Data Review

The control equipment codes in the "Primary Device Type Code" and "Secondary Device Type Code" fields were reviewed to identify invalid codes (i.e., codes that did not exist in the NIF 3.0 reference table) and missing codes (e.g., records with a null or uncontrolled code of 000 but with control efficiency data).

QA review of control efficiency data involved diagnosis of two types of errors. First, records were reviewed to identify control efficiency values that were reported as a decimal rather than as a percent value. Records with control efficiencies with decimal values were flagged as a potential error (although not necessarily an error, since the real control efficiency may be less than 1 percent). Records with a 1 percent control efficiency value were also identified for review by the S/L/T agency to determine if the value was reported as a decimal in its internal data system but rounded to 1 percent when the data were converted to NIF 3.0.

The second check identified records where 100 percent control was reported in the CE table, but the emissions in the EM table were greater than zero and the rule effectiveness value in the EM table was null, zero, or 100 percent (implying 100 percent control of emissions). Because many agencies did not populate the rule effectiveness field or a default value of zero was assigned, records with null or zero rule effectiveness values were included where the CE was 100 percent and emissions were greater than zero. For records that met these criteria, Pechan consulted with the S/L/T agency to determine if corrections were needed to any of the fields.

Start and End Date Checks

The year in the start and end date values in the PE and EM tables were reviewed to confirm consistency with the inventory year in the transmittal table, and to confirm that the end date reported was greater than the start date reported.

Annual and Daily Emissions Comparison

The S/L/T inventories were reviewed to determine if any of the following conditions existed:

- Multiple records coded at the SCC level as emission type 30, but with different start and end dates. While not a true duplicate, this may indicate an error or inclusion of both annual and seasonal values.

- Multiple records coded at the SCC level as a daily emission type (27, 29, etc.) but with different start and end dates. While not a true duplicate, this may indicate an error or just inclusion of additional types of daily emissions.

- Multiple records coded at the SCC level with the same start and end date, but different emission types. While not a true duplicate, this may indicate an error or just inclusion of additional types of daily emissions.

- Any "DAILY" type record that was missing its associated "ANNUAL" record was flagged for review.

- Any "DAILY" type record that was greater than its associated "ANNUAL" record was flagged for review.

3. Responses from S/L/T Agencies

The S/L/T agencies provided responses to questions about their data. The agencies or the Workgroups then provided direction for correcting the issues either by telephone or by e-mail. For AR and TX, QA issues were summarized in Excel spreadsheets and sent to the agencies, and the agencies provided their responses to the issues in the Excel spreadsheets. Table 7 identifies the files that document the QA issues and agency responses. The first spreadsheet in each QA Summary Report defines the remaining spreadsheets in the Excel Workbook file and provides instructions for communicating revisions.

Table 7. QA Summary Reports for S/L/T Area Source Inventories

S/L/T Agency	Excel Workbook File Name of QA Summary Report
AR	AR_QA_Report_060705.xls
TX	TX_QA_Report_071405.xls

4. Gap Filling and Augmentation

CENRAP-sponsored inventory data were added to the inventories as requested either by the S/L agencies or by the EI and Modeling Workgroups. Procedures for resolving issues with PM emissions in the comment files or to add PM emissions missing from the comment and Base A inventory files were resolved through consultation with the S/L agencies.

5. Revisions to Address Comments

The following details the revisions made to the Base A inventory:

a. Arkansas

NH_3 Emissions

To be consistent with the NH_3 categories included for the other CENRAP states, the following NH_3 categories in the CENRAP-sponsored area source inventory were added to the 2002 Base B inventory for AR:

SCC	SCC Description
2630020000	Wastewater Treatment : Public Owned : Total Processed;
2620030000	Landfills : Municipal : Total;
2806010000	Domestic Animals Waste Emissions : Cats;
2806015000	Domestic Animals Waste Emissions : Dogs;
2807020001	Wild Animals Waste Emissions : Bears : Black Bears;

2807020002 Wild Animals Waste Emissions : Bears : Grizzly Bears;
2807025000 Wild Animals Waste Emissions : Elk; and
2807030000 Wild Animals Waste Emissions : Deer.

Emissions for grizzly bears are zero; but were included in the inventory for completeness.

Agricultural Field Burning (SCCs starting with 2801500xxx)

The Base A inventory contained VOC, CO, PM10-PRI, and PM25-PRI emissions provided by AR. At AR's request, AR's state inventory was replaced with the CENRAP-sponsored inventory. The activity data for the CENRAP-sponsored inventory were developed by surveying local agricultural extension service agents which are believed to provide better spatial and temporal resolution of agricultural field burning activity than the methods that were used for AR's inventory. This change provided data for SO_2, NO_x, and NH_3 not included in AR's inventory, but removed emissions from two counties (05017 and 05125) that had emissions in AR's inventory.

Prescribed Burning for Forest Management (SCC 2810015000)

The Base A inventory contained VOC, CO, PM10-PRI, and PM25-PRI emissions for this category. At AR's request, AR's state inventory was removed from the Base B area source inventory and replaced with the point source inventory developed by CENRAP. The CENRAP-sponsored planned burning inventory did not include any emissions for area sources. This change provided data for SO_2, NO_x, and NH_3 not included in AR's inventory

Prescribed Burning of Rangeland (SCC 2810020000)

The CENRAP-sponsored planned burning inventory contains point source emissions for VOC, CO, SO_2, NO_x, NH_3, PM10-PRI, and PM25-PRI for 17 counties. This inventory was added to the Base B point source inventory.

Wildfires (SCC 2810001000)

The Base A inventory contained VOC, NO_x, CO, PM10-PRI, and PM25-PRI emissions provided by AR, and NH_3 emissions estimated using a separate methodology based on the Carnegie Mellon University (CMU) Model (Version 6.1) defaults. AR decided to remove the NH_3 emissions from the area source inventory since the NH_3 emissions were not based on their state methodology.

b. Minnesota

MN provided an area source inventory on June 3, 2005. This inventory was used to update the Base A inventory for records where there was a match on the data key between the Base A inventory and MN's June 3 file.

In addition, for the Base A modeling effort, the Midwest RPO point source inventory for wildfires (SCC 2810001000) and agricultural field burning (SCC 2801500000) was to be used for MN, and, therefore, the area source emissions data for these two categories were removed. However, it was learned that the Midwest RPO point source inventory was not being used for modeling so the 2002 area source wildfire and agricultural field burning inventories were restored to the Base B inventory. The wildfire inventory included in the Base B area source inventory originates from the 2002 NEI. The agricultural field burning inventory included in the Base B area source inventory originates from the CENRAP-sponsored planned burning inventory.

c. Texas

TX provided comments on the draft 2002 NEI and requested that this comment file be used to update the CENRAP inventory. The comment file was obtained from EPA. The comment file was compared to both the CENRAP Base A inventory and the draft 2002 NEI. As a result, there were many issues identified for which TX provided clarification on how to resolve. The QA issues, comparison of the comments to the Base A inventory and the NEI, and TX's directions for resolving the QA issues are provided is several spreadsheets in the Excel workbook file (named TX_QA_Report_071405.xls) provided with this report. After receiving TX's direction for resolving the QA issues, the submittal flags in the comments file were adjusted in order to apply the comments to the CENRAP's Base A inventory. The following provides a summary of the effects of TX's comments on the area source inventory:

- TX's comments file requested that the categories for unpaved roads (SCC 2296000000) and human perspiration (SCC 2810010000) be removed from the Base A inventory. However, since all of the other states include emissions for these categories, TX agreed that the categories should be kept in the inventory so these categories were removed from TX's comments file. The exception is that the area source inventory contained CO and VOC emissions for human perspiration for three counties that originated from the 1999 NEI. The NH_3 emissions for human perspiration are from the CENRAP-sponsored inventory and occur in all of TX's 254 counties. Therefore, per TX's request, the CO and VOC emissions were removed from the three counties.

- TX provided emissions for Mobile Sources : Highway Vehicles - Diesel : All HDDV including Buses (use subdivisions -071 thru -075 if possible) : Total: All Road Types (SCC 2230070000) that were not in the Base A inventory. The emissions for this category were added to the Base B inventory. It is not clear if the emissions for this category represent idling emissions or not. If they represent idiling emissions, these emissions are not accounted for in the nonroad inventory, thus, there would be no double counting of emissions.

- For the Base A inventory, daily PM emissions were excluded from the area source inventory because of many PM consistency issues with the daily emissions. TX provided revisions to the daily emissions; however, after adding the daily emissions to the CENRAP inventory, many PM consistency issues were identified. In addition,

for several categories it was discovered that TX revised the annual and/or daily filterable emissions but not the primary emissions resulting in the primary emissions being less than the filterable emissions. A separate Excel workbook file is provided with this report that details the issues identified and explains how TX's PM emissions were adjusted to correct for inconsistencies in the reporting of PM emissions.

d. EI and Modeling Workgroup Comments

The EI and Modeling Workgroups requested the following revisions to the area source inventory:

Natural Sources of NH_3 Emissions (SCCs starting with 27014xxxxx)

To provide consistent source category coverage across the CENRAP states for natural sources of NH_3, the emissions in the CENRAP-sponsored inventory for natural sources of NH_3 were added to the Base B inventory for AR, MN, and MO. The monthly emissions were summed to calculate annual emissions that were also added to the inventory for these three states. The emissions for these categories were already included in the area source inventory for the other CENRAP states.

Onroad NH_3 Emissions

Onroad NH_3 emissions for SCCs 2201001000 (Light Duty Gasoline Vehicles) and 2230001000 (Light Duty Diesel Vehicles) for IA, KS, and LA were removed from the area source inventory because the emissions for this category are included in CENRAP's onroad inventory.

Stage II Refueling Emissions

CENRAP revised the onroad inventory to include VOC emissions associated with Stage II refueling. Therefore, these emissions were removed from the area source inventory to avoid double-counting of emissions. The Stage II emissions removed from the area source inventory were classified under the following SCCs:

SCC	SCC Description
2501060100	Storage and Transport : Petroleum and Petroleum Product Storage : Gasoline Service Stations : Stage 2: Total
2501060101	Storage and Transport : Petroleum and Petroleum Product Storage : Gasoline Service Stations : Stage 2: Displacement Loss/Uncontrolled
2501060102	Storage and Transport : Petroleum and Petroleum Product Storage : Gasoline Service Stations : Stage 2: Displacement Loss/Controlled
2501060103	Storage and Transport : Petroleum and Petroleum Product Storage : Gasoline Service Stations : Stage 2: Spillage

PM Consistency Issues

It was discovered that the Oracle scripts run on the Base A area source inventory to identify cases where the PM10-PRI (PM25-PRI) emissions were less than the PM10-FIL (PM25-FIL) emissions did not work correctly. The scripts were corrected and tested and run on the Base B inventory. As a result, for the agricultural tilling emissions (SCC 2801000003) originating from the CENRAP-sponsored inventory, it was learned that when the Base A inventory was updated with the revised CENRAP-sponsored agricultural tilling inventory, the primary emissions got revised but the filterable emissions did not. Thus, in the Base B inventory, the filterable emissions have been revised to match the primary emissions.

6. QA Review of Final Inventory

Final QA checks were run on the revised data set to ensure that all corrections provided by the S/L/T agencies were incorporated into the S/L/T inventories and that there were no remaining QA issues that could be addressed during the duration of the project. After exporting the inventory in Oracle to an Access database in NIF 3.0, the EPA's QA program was run on the Access database and the QA output was reviewed to verify that all QA issues that could be addressed were resolved (EPA, 2004a).

The output file from the EPA's QA program run on the area source inventory and the area miscellaneous source inventory is provided in an Access 2000 database along with the Access database containing the area and area miscellaneous inventory in NIF 3.0. The following lists the remaining QA issues that were not addressed during the duration of this project:

<u>Area Source Inventory</u>

Range Errors: There are 1,408 records in the EM table with emissions that exceed the maximum emissions in the QA program for the specified pollutant.

<u>Area Miscellaneous Source Inventory</u>

Range Errors: There is one EM record in MN for SCC 2701443000 with NH3 emissions that are significantly higher than the expected maximum emissions.

D. Nonroad Source Inventory Methods

1. Data Sources

CENRAP revised its Base A inventory for the NONROAD model categories to correct the oxygen content model inputs as well as the default values used for the sulfur content of diesel. In addition, MN requested that the Midwest RPO Base J inventory be used in the revised CENRAP inventory. IA also requested that the Midwest RPO Base J inventory be used for agricultural equipment categories instead of the revised CENRAP inventory. TX, who is using its own inventory for both the Base A and B inventories, added emissions for oil field equipment. The inventories for the categories not included in the NONROAD model (i.e., aircraft,

commercial marine vessels, and locomotives) remained essentially unchanged from the Base A to the Base B inventory except for some revisions provided by TX.

The data files that the states provided for updating the Base A inventory were loaded into Oracle in NIF 3.0 into one data set. Then, the following updates were performed on the consolidated data set, if necessary:

- HAP records were removed since the inventory will support regional haze, fine PM, and ozone modeling.

- Pollutant codes were corrected to make them NIF 3.0 compliant (e.g., update PMPRI pollutant code to PM-PRI). Additionally, other codes were identified for remediation on a case-by-case basis.

- Records with a submittal flag indicating deletions (submittal_flag = 'D' or 'RD') were removed from the inventory.

- Null values in the tribal code field were updated to '000' since this field is a part of the data key that defines records as unique in all eight NIF tables.

- Added and populated the NIF plus fields listed in the previous discussion for the area source inventory.

- The CENRAP-sponsored inventory did not contain S/L agency contact information in the TR table. Therefore, the TR table was updated to include the contact information that S/L agencies provided in their area source inventories.

2. QA Review

QA review was conducted on the inventories in accordance with the QA procedures specified in the QAPP for this project (CENRAP, 2005b). The following discusses the QA checks that were completed during preparation of the consolidated data set.

a. County and SCC Coverage

The county coverage in the state inventories appeared to be reasonable for all states. The SCC coverage was difficult to evaluate simply by showing a count of the number of SCCs by state. The EI and Modeling Workgroups reviewed summaries comparing the Base B to the Base A inventory.

b. Pollutant Coverage

The pollutant coverage in the S/L/T inventories was complete for all pollutants after incorporating S/L comments.

c. Additional QA for the CENRAP Nonroad Source Inventory

The QA procedures discussed previously for the S/L/T area source inventories were applied to the nonroad inventory.

3. Responses from S/L/T Agencies

The S/L/T agencies provided responses to questions about their data. The agencies or the Workgroups then provided direction for correcting the issues either by telephone or by e-mail.

4. Gap Filling and Augmentation

CENRAP-sponsored inventory data were added to the inventories as requested either by the S/L agencies or by the EI and Modeling Workgroups.

5. Revisions to Address Comments

The following discusses the revisions made to the Base A nonroad inventory:

a. Minnesota

For the NONROAD model categories, MN elected to use the Base J inventory prepared by the Midwest RPO. This inventory includes monthly emissions. The monthly emissions were summed to calculate annual emissions, and records were added to the inventory to hold the annual emissions for supporting the development of emission summaries. The monthly emissions are used in the SMOKE IDA files for modeling.

The Midwest RPO Base J NONROAD model inventory was prepared by the state of WI. As a result, MN requested that the contact information for WI be listed in the TR table for MN.

b. Iowa

IA elected to use the CENRAP-sponsored inventory for all of the nonroad categories except for the following agricultural equipment categories:

SCC	SCC Description
22600050xx	Off-highway Vehicle Gasoline, 2-Stroke : Agricultural Equipment (2 SCCs);
22650050xx	Off-highway Vehicle Gasoline, 4-Stroke : Agricultural Equipment (11 SCCs);
22670050xx	LPG : Agricultural Equipment (3 SCCs);
22680050xx	CNG : Agricultural Equipment (3 SCCs); and
22700050xx	Off-highway Vehicle Diesel : Agricultural Equipment (11 SCCs).

For the agricultural equipment categories, IA elected to use the Midwest RPO Base J inventory because this inventory provided improvements to the temporal allocation of emissions for the agricultural sector. The Base J inventory includes monthly emissions. The monthly emissions were summed to calculate annual emissions, and records were added to the inventory to hold the

annual emissions for supporting the development of emission summaries. The monthly emissions are used in the SMOKE IDA files for modeling.

c. Texas

Oil Field Equipment Emissions

TX provided annual and daily emissions for CO, CO_2, NO_x, VOC, SO_2, PM10-FIL, and PM25-FIL for the following oil field equipment categories:

SCC	SCC Description
2265010010	Off-highway Vehicle Gasoline, 4-Stroke : Industrial Equipment : Other Oil Field Equipment;
2268010010	CNG : Industrial Equipment : Other Oil Field Equipment; and
2270010010	Off-highway Vehicle Diesel : Industrial Equipment : Other Oil Field Equipment

These emissions were added to the Base B inventory. However, primary PM emissions are needed for the inventory. TX provided authorization to change the pollutant codes from PM10-FIL to PM10-PRI and PM25-FIL to PM25-PRI.

Commercial Marine Vessels (SCC 2280000000)

TX provided revisions to the NH_3 emissions for commercial marine vessels for 17 counties and the inventory was updated with the revised emissions.

Railroad Locomotive Emissions (SCC 2285000000)

The Base A inventory did not contain NH_3 emissions for this category in TX. TX provided the NH_3 emissions that were added to the Base B inventory.

d. EI and Modeling Workgroup Comments

Correction for Double Counting of Emissions in Lancaster County, Nebraska

Lancaster County provided its own nonroad inventory for SCC 2260000000 (Off-highway Vehicle Gasoline, 2-Stroke : 2-Stroke Gasoline except Rail and Marine: All). In the Base A inventory, the CENRAP-sponsored inventory provided emissions for the more detailed SCCs and were included in the Base A inventory. After reviewing the data and consulting with the local agency, the Workgroups decided to remove the CENRAP-sponsored inventory for SCCs starting with 226 in Lancaster County to remove double-counting of emissions.

Revisions to the CENRAP-Sponsored Inventory

For the categories included in the NONROAD model, all of the states elected to use the CENRAP-sponsored inventory in the Base B inventory except for MN and TX; IA for

agricultural equipment; and Lancaster County, NE for 2-stroke gasoline vehicles. The following discusses the changes made to the CENRAP-sponsored inventory.

Revisions to Oxygen Content

The CENRAP-sponsored inventory for the NONROAD model categories was updated during March 2005 to correct the fuel oxygenate content from decimal fraction to percentage values. As a result, the NONROAD model inventory for the states that elected to use the CENRAP-sponsored inventory was replaced with the new inventory.

Revisions to Diesel Sulfur Content

The input values used for the sulfur content of diesel fuel used in the revised CENRAP NONROAD model inventory were determined to be too low and the Workgroups decided to revise the input values for this parameter to be based on the default values used by the NONROAD model. The following explains the methods applied to adjust the SO_2, PM10-PRI, and PM25-PRI emissions in the CENRAP-sponsored inventory based on adjustments to the sulfur content in diesel fuel.

The SO_2 emissions were adjusted by using the ratio of the new versus the original diesel sulfur content values, since the relationship of SO_2 to diesel fuel sulfur levels is linear. However, for PM10-PRI and PM25-PRI emissions, the adjustment is not a linear relationship. To estimate the impact of higher diesel fuel sulfur levels on PM10-PRI and PM25-PRI emissions for each state, national runs of the NONROAD model were performed using the original and new diesel fuel sulfur input values for each state.

Table 8 provides the original diesel fuel sulfur content values for seven of the CENRAP states. The NONROAD inventories for Minnesota and Texas and the agricultural equipment categories for IA were not revised because these States based their nonroad inventories on model runs that include the NONROAD model default sulfur values. The new diesel sulfur values are based on the NONROAD model default values. For diesel recreational marine engines (SCC 2282020005 and 2282020010), the NONROAD model uses a diesel sulfur content of 2,765 parts per million (ppm). For all other land-based diesel equipment, NONROAD incorporates a default diesel sulfur content of 2,457 ppm.

Table 8. Original Diesel Fuel Content

State	Original DIESEL SULFUR content, ppm
KS	330.0
AR	360.0
IA	360.0
NE	360.0
OK	360.0
LA	380.0
MO	390.0

National NONROAD model runs were performed using the four unique sulfur levels in Table 8 (i.e., 330, 360, 380, and 390), and then two national NONROAD runs were performed using the default diesel fuel sulfur content values. The results of these runs were used to develop state-specific SCC-level ratios based on the resulting PM10-PRI and PM25-PRI emissions. The SCCs to which these ratios were applied to adjust emissions are shown in Table 9.

6. QA Review of Final Inventory

Final QA checks were run on the revised data set to ensure that all corrections provided by the S/L/T agencies were incorporated into the S/L/T inventories and that there were no remaining QA issues that could be addressed during the duration of the project. After exporting the inventory in Oracle to an Access database in NIF 3.0, the EPA's QA program was run on the Access database and the QA output was reviewed to verify that all QA issues that could be addressed were resolved. The QA output is provided in an Access 2000 database along with the Access database containing the inventory in NIF 3.0.

The following lists the remaining QA issues that were not addressed during the duration of this project:

Range Errors: There are 230 records in the EM table with emissions that exceed the maximum emissions in the QA program for the specified pollutant.

Lookup Errors: There are 106,472 records in the EM table with CO_2 emissions that caused this error. CO_2 is not included in the reference table for valid NIF 3.0 pollutant codes. At the request of CENRAP, CO_2 emissions were kept in the inventory.

E. EGU 2018 Projection Year Inventory

1. Introduction

Pechan received from the Midwest RPO the 2018 IPM scenario file and extracted the data for each of the nine CENRAP states to post-process. Pechan post-processed the 2018 Integrated Planning Model (IPM) scenario data to create the mass emissions inventory for the SMOKE/IDA files. The post-processing procedure includes estimating emissions for CO, VOC, NH_3, PM10-PRI, PM10-FIL, PM25-PRI, PM25-FIL, and PM-CON. Emissions for 21 temporal-pollutant combinations are estimated since there are seven pollutants and three temporal periods (summer season, winter season, July day). Note that annual SO_2 and annual, summer season, and July day NO_x emission values are provided in the initial IPM scenario file. First, annual emission are estimated by applying an SCC-based pollutant-specific uncontrolled emission factor (that may include sulfur and/or ash content factor) to fuel quantity (that is obtained from the annual heat input provided in the IPM run and default fuel-based heat contents), control removal efficiency, and a units conversion factor.

Table 9. NONROAD Diesel SCCs in the CENRAP-Sponsored Inventory for which the Sulfur Value will be adjusted to the NONROAD Model Default Value

SCC*	SCC Description	NONROAD Model Default Diesel Fuel S level, ppm**
2270001060	Mobile Sources : Off-highway Vehicle Diesel : Recreational Equipment : Specialty Vehicles/Carts	2457

* Unique list of SCCs is from CENRAP-sponsored inventory for all States except MN and TX.
** Marine diesel fuel S level assumed higher than land-based diesel fuel.

To obtain the needed temporal emissions, summer season emissions are estimated by multiplying the annual emissions by a ratio of the summer season to annual heat input; winter season emissions are estimated by subtracting the summer season emissions from the annual emissions; and summer day emissions are estimated by multiplying the annual emissions by a ratio of the July day to annual heat input.

Table 10 presents the CO, VOC, NH_3, PM10-FIL, and PM25-FIL emission factors by SCC. Table 11 presents the PM-CON emission factors by SCC. For PM10-FIL and PM25-FIL, control efficiencies (that are obtained using an EPA-approved method) are applied to the uncontrolled emissions. PM-CON is estimated using heat input (included in the IPM run) and emissions factors. PM10-PRI (and PM25-PRI) are obtained by summing PM-CON and PM10-FIL (PM-CON and PM25-FIL) emissions.

The post-processing methodology also includes the following steps:

Step 1: Adding data for all units.

SCCs were assigned for all units; unit/fuel/firing/bottom type data were used for existing units' assignments, while only unit and fuel type were used for generic units' assignments. Latitude-longitude coordinates were assigned, first using the EPA-provided data files, secondly using the September 17, 2004 Pechan in-house latitude-longitude file, and lastly using county centroids. These data were only used when the data were not provided in the 2002 NIF files. Stack parameters were attached, first using the EPA-provided data files, secondly using a March 9, 2004 Pechan in-house stack parameter file based on previous EIA-767 data, and lastly using an EPA June 2003 SCC-based default stack parameter file. These data were only used when the data were not provided in the 2002 NIF files. Plant ID (within State and county), point ID, process ID, and stack ID were then attached, first using the EPA-provided data files, or secondly using Pechan-generated defaults: the point ID is assigned the value of the given boiler ID preceded by '#', unless the boiler ID has a length of six [the length for the point ID], in which case the left-most character is replaced with '#'); and the default Pechan process ID is '01'. Default stack IDs within a plant are assigned for each unique stack height-diameter combination; the default Pechan stack ID is of the form '4N'. The process ID and stack ID default data were only used when the data were not provided.

[1] A means the ash content (percentage value) of the fuel is multiplied by the emission factor value shown in this table.

[2] From Factor Information and REtrieval (FIRE) 6.24, the equation for this PM10-FIL EF is [5.9*(1.12*S+0.37)].

[3] From FIRE 6.24, the equation for this PM25-FIL EF is [4.3*(1.12*S+0.37)].

Note that (1) -9 indicates that an emission factor is not available for the SCC and pollutant combination; and (2) for SCCs beginning with 101001, 101002, or 101003 (coal), 101008 (coke), 101009 (wood), 101011 (bagasse), 101012 (solid waste), 101019 (synfuel), 101020 (waste coal), or 101012 (agr. byproduct), emission factors are in pounds per ton; for SCCs beginning with 101004, 101005, and 201001 (oil), 101010 (propane/butane), 101013 (liquid waste), 101016 (methanol), 101021 (other oil), or 201009 (kerosene/jet fuel), emission factors are in pounds per thousand gallons; for SCCs beginning with 101006 or 201002 (natural gas), 101007 (process gas), 101018 (hydrogen), or 201003 (IGCC) emission factors are in pounds per million cubic feet.

Table 11. PM Condensable Emissions Factors (EF) for Electricity Generating Units

Fuel	Applicable Source Classification Codes	PM Condensable Emission Factor (PMCDEF) in lb/MMBtu
Coal (including waste coal and syn coal)*	10100204, 10100205, 10100224, 10100225, 10100304, 10100306	0.0400
	10100217, 10100218, 10100237,10100238, 10100317, 10100318, 10102018	0.0100
	10100201, 10100202, 10100203, 10100212, 10100221, 10100222, 10100223, 10100226, 10100301, 10100302, 10100303, 10101901, 10102001	0.02**
	10100201, 10100202, 10100203,10100212, 10100221, 10100222,10100223, 10100226, 10100301, 10100302, 10100303, 10101901, 10102001	(0.1 * sulfur content [as a decimal] - .03)***
Light Oil (Distillate, Diesel)	10100401 - 10100499	0.0100
Heavy Oil (Residual)	10100501 - 10100599	0.0090
Natural Gas	10100601 - 10100699	0.0057
Other Process Gases	10100701 - 10100799	0.0056
Petroleum Coke	10100801 - 10100899	0.0100
Wood, Biomass (including Black Liquor), Waste/Refuse	10100901 - 10100999, 10101201 - 10101299, 10101304	0.0170
LPG (Propane, Butane)	10101001 - 10101099	0.0056
Other Liquid Waste/Oil, Methanol	10101301, 10101302, 10101305, 10101306, 0101307, 10101308, 10102101, 10101601	0.0090

* If the emission factor is less than 0.01, then it is set equal to 0.01.
** AND there is either an SO2 FGD or a PM wet scrubber.
*** And there is any PM control other than a wet scrubber and there is no SO_2 control, OR SCC = 10100222 and there is no PM control.
Note that PM10-PRI = PM10-FIL + PM-CON and PM25-PRI = PM25-FIL + PM-CON.

Step 2: Siting generic units using an EPA-approved electronic method.

Generic aggregates, which consist of IPM-designated "planned/committed" units as well as "new" units produced by the IPM model are transformed into units similar to the existing units in terms of the available data. The generic aggregates are split into smaller generic units based on their unit types and capacity, are provided a dummy ORIS unique plant and boiler ID, and are given a county FIPS code based on an algorithm that sites each generic by assigning a sister plant that is in a county based on its attainment/nonattainment status. Within a state, plants (in county then ORIS plant code order) in attainment counties are used first as sister sites to generic units, followed by plants in PM nonattainment counties (as of January 2004), followed by plants in 8-hour ozone nonattainment counties (as of April 2004).

Step 3: Deriving defaults using the same methodology previously approved by the Midwest RPO and Visibility Improvement State and Tribal Association of the Southeast (VISTAS).

Additional data were required for estimating VOC, CO, PM10-FIL, PM25-FIL, PM-CON, and NH_3 emissions for all units. Thus, ash and sulfur contents were assigned by first using 2002 EIA-767 values for existing units or SCC-based defaults; PM10-FIL and PM25-FIL efficiencies were obtained from the 2002 EGU NEI that were based on 2002 EIA-767 control data and the PM Calculator program (a default of 99.2 percent is used for coal units if necessary); fuel use was back calculated from the given heat input and a default SCC-based heat content; and emission factors were obtained from an EPA-approved October 7, 2004 Pechan emission factor file based on AP-42 emission factors. Note that this updated file is not the one used for estimating emissions for previous EPA post-processed IPM files.

Step 4: Adding in S/L agency emissions inventory identifiers from the updated CENRAP crosswalk.

The previous crosswalk file was compared to the Base B point source inventory and updated to as needed to ensure correct matching of the codes in the IPM file to state IDs in the NIF 3.0 inventory file. The revised crosswalk file was then used to obtain state and county FIPS codes, plant IDs (within State and county), and point IDs. If the state and county FIPS codes, plant IDs and point IDs were in the 2002 NIF tables, then the process IDs and stack IDs were obtained from the NIF; otherwise, defaults, described above, were used.

Step 5: Transforming the data into annual SMOKE/IDA formatted text files for use by the modelers (see section II.E.4).

2. Data Sources

There are several data sources used during the post-processing procedure. These include the following:

- Records from the nine CENRAP states from one Midwest RPO/VISTAS IPM "second round" parsed file, VISTASII_PC_1f_FossilUnits_2018 (To Client).xls

$	The updated CENRAP crosswalk

$	Two EPA-approved emissions factor in-house file (Tables 10 and 11) for estimating annual VOC, CO, NH_3, PM10-PRI, PM10-FIL, PM25-PRI, PM25-FIL, and PM-CON emissions

$	Other files used in previous IPM run post-processing (e.g., power plant latitude-longitude file, SCC assignment file, fuel-based heat content file, EIA-767-based stack parameters file, and EPA-approved default stack parameters file).

### 3.	QA Review

Pechan performed QA of the inventory by extracting the records for the CENRAP states from the 2018 IPM run and then checking to verify that all of the records are included in the CENRAP crosswalk and, if not, flagging them so that they are properly accounted for in the post-processing. After the post-processing was completed, and the data were transformed into their proper format, Pechan compared the initial (from the IPM file) and final (from the SMOKE/IDA files) NO_x emission tons -- annual [summer plus winter season], summer season, summer day -- and SO_2 annual [summer plus winter season] emission tons -- for each State and for the nine State total to ascertain that they did not change values; they did not.

### 4.	SMOKE/IDA Files

The 2018 inventory was formatted as SMOKE/IDA summer and winter files. The file structures are delineated in Tables 12 and 13.

### 5.	Emissions Summary

Table 14 provides a summary of the summer season, summer day, and winter season emissions calculated for the 2018 EGU inventory and included in the SMOKE IDA files.

Table 12. CENRAP SMOKE/IDA Summer Season File Structure

1. Selected from the NIF EM table using corresponding segment ID from using the segment ID selection process. Defaults taken from IPM process and are either from EPA approved files or are Pechan defaults (41, 42, 43, etc).
2. Segment ID selection process used to determine which ID is used. Process consists of taken the segment ID from the NIF EM table with the highest emissions. Only the seven relevant pollutants are used and follow a hierarchy of NO_x+SO_2 first, Primary PM_{10}+Primary $PM_{2.5}$ second, and CO+NH_3+VOC last.
3. Selected from the NIF SI table using a plant's STID+CYID+PLANTID or a default of 4911.

F. Preparation of SMOKE/IDA and RPO Data Exchange Protocol (NIF 3.0) Formats

This section describes the inventory and SMOKE emission processor files prepared under this project. The Excel Workbook file named "CENRAP Inventory File Documentation 08225.xls" provides the names of the files delivered, as well as other file information useful for transferring data to air quality modeling centers. This Excel Workbook file is provided along with this report. Table 15 provides a summary of the files delivered.

Table 15. Summary of Mass Emissions and SMOKE Input Files

S/L/T Agencies Included in Files	NIF 3.0 File Name Containing Mass Emissions Inventory (Access 2000 Database Files)	Temporal Period of Mass Emissions Inventory	SMOKE/IDA File Name	Temporal Period of Emissions in SMOKE/IDA File	Notes
Point Source Inventory for 2002					
AR, IA, KS, LA, MN, MO, NE, OK, TX, Fond du Lac Band of the Minnesota Chippewa Tribe (Tribal Code 405), and the Leech Lake Band of the Ojibwe Tribe (407)	CENRAP_2002_Point_082205.mdb	Annual	CENRAP_POINT_SMOKE_INPUT_ANNUAL_DAILY_072505.txt	Annual for all agencies; Daily for MO and TX	Includes all sectors supplied by S/L/T agencies. Tribal inventories include Fond du Lac Band of the Minnesota Chippewa and the Leech Lake Band of the Ojibwe. Local inventories include Lancaster County (Lincoln) and Douglas County (Omaha), NE.
MO and TX	CENRAP_2002_Point_Daily_Missouri_Texas_071405.mdb	Daily	CENRAP_POINT_SMOKE_INPUT_ANNUAL_DAILY_072505.txt	"	Daily emissions for MO and TX are included in the SMOKE/IDA file containing annual emissions for all CENRAP agencies, but placed in a NIF 3.0 file separate from the NIF 3.0 file containing the annual emissions.
Point Source Inventory for 2108					
AR, IA, KS, LA, MN, MO, NE, OK, TX	None		CENRAP_2018_Summer_081105.txt, CENRAP_2018_Winter_081105.txt	Summer season, Winter season	2018 EGU summer season and winter season emissions.
Nonroad Source Inventory for 2002					
AR, IA, KS, LA, MN, MO, NE, OK, TX	CENRAP_2002_Nonroad_071305.mdb	Annual, Monthly, and Daily	CENRAP_NONROAD_SMOKE_INPUT_ANN_071305.txt	Annual	Includes NONROAD Model Categories and Aircraft, Commercial Marine Vessels, and Railroad Locomotives. NONROAD Model inventory is from revised CENRAP-sponsored inventory except for TX (who supplied its own NONROAD Model Inventory), MN (who used the Midwest RPO Base J inventory for all NONROAD Model categories), and IA (who used the Midwest RPO Base J inventory for agricultural equipment). MN included commercial and military aircraft and auxiliary power units in its point source inventory; therefore, the nonroad inventory does not contain emissions for these categories in MN.
MN and IA	"	"	CENRAP_NONROAD_SMOKE_INPUT_MONTH_JAN_071305.txt	Monthly Emissions x 12	Includes monthly emissions for MN (all NONROAD Model categories) and IA (agricultural equipment categories) from the Midwest RPO Base J inventory. Monthly emissions are multiplied by 12 (months).
Nonroad Source Inventory for 2002 (continued)					

Table 15 (continued)

S/L/T Agencies Included in Files	NIF 3.0 File Name Containing Mass Emissions Inventory (Access 2000 Database Files)	Temporal Period of Mass Emissions Inventory	SMOKE/IDA File Name	Temporal Period of Emissions in SMOKE/IDA File	Notes
MN and IA	“	“	CENRAP_NONROAD_SMOKE_INPUT_MONTH_FEB_071305.txt	Monthly Emissions x 12	Includes monthly emissions for MN (all NONROAD Model categories) and IA (agricultural equipment categories) from the Midwest RPO Base J inventory. Monthly emissions are multiplied by 12 (months).
MN and IA	“	“	CENRAP_NONROAD_SMOKE_INPUT_MONTH_MAR_071305.txt	Monthly Emissions x 12	Includes monthly emissions for MN (all NONROAD Model categories) and IA (agricultural equipment categories) from the Midwest RPO Base J inventory. Monthly emissions are multiplied by 12 (months).
MN and IA	“	“	CENRAP_NONROAD_SMOKE_INPUT_MONTH_APR_071305.txt	Monthly Emissions x 12	Includes monthly emissions for MN (all NONROAD Model categories) and IA (agricultural equipment categories) from the Midwest RPO Base J inventory. Monthly emissions are multiplied by 12 (months).
MN and IA	“	“	CENRAP_NONROAD_SMOKE_INPUT_MONTH_MAY_071305.txt	Monthly Emissions x 12	Includes monthly emissions for MN (all NONROAD Model categories) and IA (agricultural equipment categories) from the Midwest RPO Base J inventory. Monthly emissions are multiplied by 12 (months).
MN and IA	“	“	CENRAP_NONROAD_SMOKE_INPUT_MONTH_JUN_071305.txt	Monthly Emissions x 12	Includes monthly emissions for MN (all NONROAD Model categories) and IA (agricultural equipment categories) from the Midwest RPO Base J inventory. Monthly emissions are multiplied by 12 (months).
MN and IA	“	“	CENRAP_NONROAD_SMOKE_INPUT_MONTH_JUL_071305.txt	Monthly Emissions x 12	Includes monthly emissions for MN (all NONROAD Model categories) and IA (agricultural equipment categories) from the Midwest RPO Base J inventory. Monthly emissions are multiplied by 12 (months).
MN and IA	“	“	CENRAP_NONROAD_SMOKE_INPUT_MONTH_AUG_071305.txt	Monthly Emissions x 12	Includes monthly emissions for MN (all NONROAD Model categories) and IA (agricultural equipment categories) from the Midwest RPO Base J inventory. Monthly emissions are multiplied by 12 (months).
MN and IA	“	“	CENRAP_NONROAD_SMOKE_INPUT_MONTH_SEP_071305.txt	Monthly Emissions x 12	Includes monthly emissions for MN (all NONROAD Model categories) and IA (agricultural equipment categories) from the Midwest RPO Base J inventory. Monthly emissions are multiplied by 12 (months).
Nonroad Source Inventory for 2002 (continued)					

Table 15 (continued)

III. SUMMARIES OF EMISSIONS INVENTORIES FOR THE CENRAP REGION

Summaries of emissions were prepared from the emission inventory files for each sector and for all sectors combined. The summaries are provided in an Access 2000 database named "CENRAP Base B Emission Summaries_082205.mdb". The same summaries are also provided in an Access 97 database named "CENRAP Base B Emission Summaries_082205_Acc97.mdb".

Table 16 identifies and briefly describes the contents of the emissions summary tables included in the database. The nonroad source sector summaries include emissions for aircraft, commercial marine vessels, and locomotives as well as the emissions from the NONROAD model categories. The onroad summaries were prepared from the revised CENRAP-sponsored inventory for onroad sources. Tables 1G, 2C, 3C, 4C, and 5C include the data source code for the area, point, nonroad, and onroad sectors to assist in identifying the origin and year of emissions inventory data. The data source codes were defined previously in Chapter II of this report.

The summaries in Appendix A of this report are taken from the emissions summary Table 1D. These summaries include natural sources NH_3 emissions and the biogenic wind erosion PM10-PRI and PM25-PRI emissions; thus, the emission totals in Appendix A match the totals in Chapter I, Table 1 of this report. Note, however, that the emissions for natural sources and wind erosion are excluded from Tables 2a through 2e of Chapter I.

A second Access 2000 database named "CENRAP Emission Summaries_Compare Base B to A_082205.mdb" provides summaries that compare the emissions in the Base B inventory to the Base A inventory. These summaries are provided for the "All Sector" Tables 1A through 1F series of summaries. These summaries are useful for identifying the states and sectors where annual emissions changed significantly as a result of the comments received on the Base A inventories for all of the sectors. This database is also provided in Access 97 format (named "CENRAP Emission Summaries_Compare Base B to A_082205_Acc97.mdb").

IV. METHODS FOR AREAS OUTSIDE OF THE CENRAP REGION

A. Data Sources and Augmentation Procedures

This task involved calculating fire emissions and source parameters given fuel, location, and time period information for the Province of Ontario, Canada. CENRAP made the "raw" data for these fires available at http://www.cenrap.org/emission_document.asp. The names of the specific files made available include the following:

"Ontario Fires over 100 ha 1992- 2002 WFR.xls"
"Ontario Fires over 100 ha 1992 -2002 WFR-EXPLAIN.xls"

The files contain data for 54 fires that occurred in Ontario during the year 2002. Information on the data code abbreviations, data definitions, and data units used in the raw data files was obtained from Mr. Rob Luik (Data Management Specialist) at the Ontario Ministry of Natural Resources (Rob.Luik@MNR. gov.on.ca). Tables 17 and 18 provide definitions of the fuel types and other data provided in the raw data files.

B. Development of BlueSky Inputs

Emissions for each fire were estimated using the Emission Production Model (EPM)/CONSUME within the BlueSky framework. To run EPM/CONSUME, the following information was needed for each fire:

- Fire identification code;
- Latitude and longitude of the fire;
- Start and end dates of the fire;
- Daily size of the fire; and
- Fuel loading information.

A fire identification code is needed to track individual fires throughout the processing. The unique fire identification code was created for each fire by concatenating the FIRE_NUMBER and CUR_DIST fields of the original data. The fire identification code also contains the FIPS code of the fire; this information is not used by BlueSky but is needed by BlueSky2Inv, the utility program that converts the BlueSky output to the SMOKE inventory format. The FIPS code 135000 was used for all fires with longitudes east of –90°, and FIPS code 135059 was used for fires west of –90°. These FIPS codes were used to ensure that the fires would be assigned the correct time zones in later SMOKE processing.

The DISC_DATE field (discovery date) was used as the start date for each fire. While the original data did provide start dates earlier than the discovery date for some fires, the discovery date was used for all fires for consistency. Similarly, the OUT_DATE field was used from the original data as the end date for each fire. Some of the dates provided in the original data included hourly information. In all cases, the hourly information was not used leaving all data at a daily resolution.

ATTACK_DATE	Attack date
BHE_DATE	Being Held date
UCO_DATE	Under Control date
OUT_DATE	Out date

The total number of days each fire burned was determined using the start and end date for each fire. For each fire, the size of the area burned each day was estimated. The original data included the final size of each fire which was used to determine the total area burned by each fire. Rather than introduce additional assumptions about the daily fire size, it was assumed that the area burned each day was constant over all days. Therefore, the total size of the fire was divided by the total days the fire burned to get an estimate of the daily fire size. The area burned by each fire was converted from hectares to acres as needed by EPM/CONSUME.

For each fire, fuel loading data must be provided to indicate the type of fuels available for burning so that the emissions can be estimated. The original data included fuel type information for each fire using the Canadian Forest Fire Danger Rating System (CFFDRS) fuel types. Descriptions of each fuel type are available at http://fire.cfs.nrcan.gc.ca/research/environment/ cffdrs/fbpfuels_e.htm. Detailed fuel information for these types could not be identified; therefore, the CFFDRS types were mapped to the types used by the National Fire Danger Rating System (NFDRS). Information about these fuel types is available at http://www.fs.fed.us/fire/planning/ nist/nfdr.htm. Table 19 shows how the CFFDRS fuel types in the original data were mapped to the NFDRS fuel types, and shows the total number of fires for each fuel type. Table 20 shows the default fuel loading factors included in BlueSky for each NFDRS fuel type.

Table 19. Mapping of Canadian to National Fire Danger Rating System Fuel Types

Canadian Forest Fire Danger Rating System	National Fire Danger Rating System	Number of Fires
C2: Boreal Spruce	Q: Dense Alaskan black spruce and shrubs	36
C3: Mature Jack Pine	C: Open pine perennial grass understory	4
C4: Immature Jack Pine	G: Dense conifer with heavy downed and duff	1
C6: Conifer Plantation	U: Closed western long-needled pines	4
M2: Boreal Mixedwood – Green	R: Hardwoods after leafout	2
M3: Dead Balsam Fir Mixedwood – Leafless	G: Dense conifer with heavy downed and duff	1
M4: Dead Balsam Fir Mixedwood - Green	G: Dense conifer with heavy downed and duff	1

Table 20. Default Fuel Loading Factors Associated with National Fire Danger Rating System Fuel Types

	Tons/Acre of Fuel by Fuel Size in Inches					
Type	0 – 0.25	0.25 – 1	1 – 3	3 – 9	9 – 20	20+
C: Open pine	1.0	2.2	0.0	0.0	0.0	0.0
G: Dense conifer	2.9	2.3	5.6	13.2	0.0	0.0
Q: Dense spruce	3.0	3.5	3.0	1.0	0.0	0.0
R: Hardwoods	0.6	0.6	0.6	0.0	0.0	0.0
U: Closed pines	1.5	1.5	1.0	0.0	0.0	0.0

Three of the 54 fires in the raw data files did not have any latitude and longitude coordinates or any fuel type data. Therefore, the three fires were excluded from the inventory. The three fires combined accounted for less than 1 percent of the total area burned by all 54 fires. The raw data files did not contain any fuel type data for two other fires. The coordinates provided for these two fires were matched with the BELD3 database to determine the dominant vegetation type at the location of each fire. In both cases, the vegetation type was USGS conifer, which was mapped to NFDRS Type U (closed western long-needled pines).

All other inputs to EPM/CONSUME including meteorology-based parameters used the BlueSky defaults.

C. Development of SMOKE Inventory Files

After running BlueSky with the prepared inputs, the SMOKE utility program "BlueSky2Inv" was used to convert the EPM/CONSUME output to the inventory files needed by SMOKE. Since the EPM/CONSUME output is daily, BlueSky2Inv creates a PTHOUR file containing the daily emissions for each fire. The data included in the PTHOUR file are daily values for the fire's area (AREA), heat flux (HFLUX), $PM_{2.5}$, PMC (calculated as $PM_{10} - PM_{2.5}$), CO, and total organic gases (TOG) (calculated as methane + non-methane hydrocarbons).

BlueSky2Inv also creates an annual IDA inventory file. This file does not contain any emissions data but serves as a master list of sources. The annual inventory also contains the latitude and longitude of each fire. For all sources, BlueSky2Inv assigned the SCC 2810001000 (Miscellaneous Area Sources; Other Combustion; Forest Wildfires; Total).

Since BlueSky2Inv was developed for US inventories; therefore, the "#COUNTRY" headers in both output inventories were changed to CANADA.

D. SMOKE Input Files

The draft inventory files were provided to CENRAP via email on July 19, 2005. The following files were delivered:

- ptinv.ontario_fires.2002.txt: annual fire event inventory in IDA format
- ptday.ontario_fires.2002.txt: daily fire emissions inventory
- monthly.ontario.2002.txt: a report file summarizes the emissions by fire and by month. This report could be used to build monthly or annual fire emissions inventories if needed.

E. Emissions Summary

Table 21 provides a summary of monthly emissions calculated for 2002 Ontario fires. Emissions were estimated for CO, $PM_{2.5}$, coarse PM (PMC) and TOG. Note that the modeling framework selected for estimating emissions does not include factors for estimating NO_x, SO_2, and NH_3.

Table 21. Summary of 2002 Ontario Fire Emissions by Month

Month	Number of Fires	Area Burned (Acres)	CO (tons)	$PM_{2.5}$ (Tons)	PMC (Tons)	TOG (Tons)
May	2	247	41.5	4.3	0.5	3.7
June	9	13,436	12,368.8	1,140.8	118.3	743.6
July	51	209,954	183,407.5	16,807.9	1,734.3	10,810.4
August	39	170,831	146,623.3	13,445.3	1,386.7	8,649.9
September	10	27,950	23,709.5	2,169.1	223.2	1,397.8
October	1	993	878.3	80.0	8.2	51.5
Totals		423,411	367,028.8	33,647.4	3,471.3	21,656.8

CHAPTER I. INTRODUCTION

The purpose of this project was to prepare emission growth and control factors that can be applied to the Central Regional Air Planning Association (CENRAP) 2002 base year emission inventory to obtain a 2018 emissions inventory for the CENRAP region. The CENRAP region includes the States and Tribal areas of Arkansas, Iowa, Kansas, Louisiana, Minnesota, Missouri, Nebraska, Oklahoma, and Texas. In addition to the CENRAP States, additional factors were compiled under this project to include the entire CENRAP modeling domain. This includes projected emissions data or projection year growth and control factor data from the other Regional Planning Organizations (RPOs), Canada, and Mexico. All data products were prepared in SMOKE-compatible format.

These projection year growth and control factor data will be used to support air quality modeling and State Implementation Plan (SIP) development and implementation activities for the regional haze rule and fine particulate matter (PM) and ozone National Ambient Air Quality Standards (NAAQS). The data are applicable to all source categories and pollutants included in the CENRAP 2002 emission inventory. This includes the following pollutants: sulfur oxides (SO_x), oxides of nitrogen (NO_x), volatile organic compounds (VOC), carbon monoxide (CO), ammonia (NH_3), and particles with an aerodynamic diameter less than or equal to a nominal 10 and 2.5 micrometers (i.e., primary PM_{10} and $PM_{2.5}$).

This Technical Support Document (TSD) explains the data sources that E.H. Pechan & Associates, Inc. (Pechan) used and the procedures Pechan followed in developing the necessary growth and control data for this project. Appendix A of this document contains the Methods Document that was prepared under this project. The purpose of this TSD is not to duplicate the information contained in that document, but to supplement it with the actual data obtained under this project and to note areas where the methods were modified from those included in the Methods Document. Chapter II of this document presents information on the control factors and growth factors that Pechan developed for the CENRAP States. The methods are presented separately for each of the major source categories. Chapter III of this document presents the data sources and methods that Pechan used to compile the data for areas outside of the CENRAP States, including other RPOs and Canada and Mexico. Issues of concern are discussed in Chapter IV and references are included in Chapter V. Appendix A contains the Methods document prepared for this project and Appendix B contains the Quality Assurance Project Plan for this work.

This TSD is accompanied by a set of SMOKE-formatted modeling files, as well as a set of State-level Excel spreadsheets. The State spreadsheets are included for area source controls, point source controls, VMT growth, area and point source growth factors, and nonroad emissions. These spreadsheets summarize data contained in the modeling files, in a more readable format. The control files also contain 2002 emissions, in most cases, so that the effects of the controls can be estimated, using the 2002 emissions as a base (e.g., without the growth factors applied). These spreadsheets can be used by the States to review the inputs to the SMOKE modeling in more detail and can be used to help in quality assuring the emissions calculated by the SMOKE model.

CHAPTER II. DEVELOPMENT OF GROWTH AND CONTROL FACTORS FOR THE CENRAP STATES

A. DEVELOPMENT OF GROWTH FACTORS FOR NON-EGU POINT AND AREA SOURCES

This chapter identifies the data sources and methods that Pechan used to develop point and area source emission activity growth factors to support 2018 emission projections for CENRAP. Table II-1 identifies the Regions and States for which Pechan developed emission activity growth factors. It is important to note that this section describes the development of growth factors for all point and area sources in the CENRAP base year inventory. For the EGU sector, CENRAP will be using emission data projected by the Integrated Planning Model (IPM). These IPM projections are not expected to be completed until late in the summer of 2005. Because these data were not available at the time Pechan prepared the point source growth factors, the growth factors Pechan prepared included growth factors for all EGU source classification codes (SCCs) that were included in the base year inventory as described in this section. When the IPM model runs are completed, the IPM-based emissions should overwrite EGU emissions projected with these growth factors. As such, these EGU growth factors should be considered as temporary placeholders.

Table II-1. Regions and States Included in Emission Activity Growth Factor Files

Region	States	Region	States	Region	States
CENRAP	Arkansas	MANE_VU	Connecticut	Midwest RPO	Indiana
	Iowa		District of Columbia		Illinois
	Kansas		Delaware		Michigan
	Louisiana		Massachusetts		Ohio
	Minnesota		Maryland		Wisconsin
	Missouri		Maine		
	Nebraska		New Hampshire		
	Oklahoma		New Jersey		
	Texas		New York		
			Pennsylvania		
			Rhode Island		
			Vermont		

NOTE: growth factors are also included for offshore emission source categories located in the Gulf of Mexico.

In addition to all point and area source categories, it was necessary to develop growth factors for the following nonroad source categories because they are not included in EPA's NONROAD model: railroads, commercial marine vessels, and aircraft.

To identify the State/County/SCC combinations for which growth factors are required, Pechan summarized the CENRAP 2002 base year inventory (Pechan and CEP, 2005) and the base year inventories for MANE-VU and Midwest RPO available from CENRAP's visibility modeling

website (CENRAP, 2005).[1] A zip file containing all of the data files titled “NonCENRAP States Inventory SMOKE Input Files” was available at CENRAP’s website (see Table II-2 for list of files contained in the zip file). Because some of these files provide information for States outside of the geographic area of interest, the State/County/SCC summary did not include all of the States reported in these non-CENRAP State files.

Table II-2. Base Year Inventory Files for Non-CENRAP States

File Name	Contents
arinv_nei02_032404_MW_MVU_NOnh3.ida.txt	Midwest RPO and MANE-VU area sources excluding agriculture-related ammonia SCCs and fugitive dust emissions
ar_dust_phaseii_22mar04_USnoCENRAP.ida	U.S. fugitive dust inventory (excluding road dust)
nr_2002_23mar04_MW_MVU.ida	CENRAP, Midwest RPO, and MANE-VU 2002 nonroad mobile inventory
rdinv.pvd_US_${season}02_ida.txt	U.S. annual 2002 paved road dust inventory
rdinv.unp_US_${season}02_ida.txt	U.S. seasonal 2002 unpaved road dust inventory
ptinv_2002NEI_041504_MW_MVU.ida.txt	CENRAP, Midwest RPO, & MANE-VU point source inventory

In addition to the CENRAP web-site files noted above, Pechan was supplied with a separate file that listed SCCs used to report agriculture-related ammonia emissions in the non-CENRAP States (Omary, 2005). Because this file did not contain any geographic identifiers, Pechan developed a comprehensive list of MANE-VU and Midwest RPO State/SCC combinations that may exist in each region’s base year inventory.[2]

The following sections describe the data and methods that were used to prepare emission activity growth factors for the State/County/SCC combinations of interest.

1. Overview

For most source categories, Pechan developed default emission activity growth factors utilizing data and methods that are expected to be incorporated into the final Economic Growth Analysis System (EGAS) Version 5.0. CENRAP selected EGAS 5.0-based growth factors over the growth factors available from EGAS 4.0 because the EGAS 5.0 growth factors will be based on the latest set of economic/demographic projections developed by Regional Economic Models, Inc. (REMI) and the latest energy forecasts prepared by the U.S. Department of Energy (DOE) (Houyoux, 2004; DOE, 2004). In addition, the crosswalk between SCCs and emission activity

[1]Note that projections/growth factors for the following regions were not developed because they were available from other studies: Visibility Improvement State and Tribal Association of the Southeast (VISTAS) and Western Regional Air Partnership (WRAP).

[2]Except for oil and gas production, Pechan did not have access to offshore-specific projections data. Therefore, Pechan assumed that Texas area growth factors could be used to represent growth in all offshore non-oil and gas production SCCs.

growth indicators and the regression equations relating socioeconomic indicators to emission activity levels will both be refined in EGAS 5.0. Furthermore, the REMI economic models in EGAS 5.0 allocate national economic activity based on relative production costs at the 53-sector level rather than the 14-sector level used in EGAS 4.0. Local relative factor costs may be substantially different for a given detailed industry within one of the 14-sectors included in the REMI models in EGAS Version 4.0. However, the 14-sector models cannot model this distinction, since they are constrained by data specified at this level of detail. More accurate regional forecasts result from the more detailed representation of relative cost competitiveness that is available from the EGAS 5.0 REMI models.

Because EGAS represents a default set of growth factors, Pechan investigated alternatives to the EGAS default indicators for the highest-emitting point, nonpoint, and nonroad SCCs in the base year inventory for the CENRAP States.[3] Based on this review, Pechan identified a number of alternatives that were deemed preferable to the EGAS defaults, including:

- Use of regression equations developed for EGAS 5.0, but not incorporated into the beta version (for architectural coating and commercial pesticide application SCCs);[4]
- Replacement of suspect beta EGAS 5.0 growth factors with values deemed to be more reasonable;[5]
- Use of county-level population projections available from each State in the CENRAP region;
- Use of *Annual Energy Outlook* (AEO) projections (for oil and gas production SCCs);
- Use of average historical values (for prescribed burning SCCs);
- Extrapolation of historical trend (for unpaved road SCCs);
- Use of United States Department of Agriculture (USDA) projections of planted acreage for major crops (for crop tilling SCCs);
- Use of onroad vehicle miles traveled projections (for paved road SCCs); and
- Use of USDA livestock projections (for swine, cattle and calves, and poultry SCCs).

[3]Note that this discussion only applies to nonroad SCCs that are not included in the NONROAD model. A separate Pechan memorandum addressed refinements to the NONROAD model default growth information.

[4]The current EGAS 5.0 design does not support incorporation of some of the emission activity forecasting equations that Pechan developed for use in EGAS 5.0.

[5]The beta version of EGAS 5.0 has not yet undergone beta testing to identify/fix suspect values.

Further details on these emission activity growth surrogates are provided in the following section.

2. Alternative Forecast

There are a number of problems and shortcomings of the beta version of EGAS 5.0 that was available during this project's period of performance. Although some of these limitations were known at the time the beta version was released in November 2004 (see http://www.epa.gov/ttn/ecas/EGAS5limitations.pdf), a number of additional problems have since been identified. Therefore, except as noted below, point and non-point source emission projections rely on the methods and data that are expected to be incorporated into the final version of EGAS 5.0 rather than the information in the beta version. The following subsections summarize differences between the information developed for this effort and the EGAS 5.0 beta version.

a. Use of Regression Equations Not Yet Incorporated into EGAS

For certain sectors, Pechan utilized regression equations developed for EGAS 5.0, but not incorporated into the beta version. For the SCCs displayed in Table II-3, Pechan replaced the beta EGAS 5.0 growth factors based on REMI socioeconomic data with growth factors derived from the emission estimation approaches developed for EGAS 5.0 that have yet to be incorporated. The following sections identify the emission activity forecasting methods that were applied to these SCCs.[6]

Table II-3. Additional Source Categories Utilizing Regression Equation Approach

SCC	SCC Description
2401001000	Solvent Utilization; Surface Coating; Architectural Coatings; Total: All Solvent Types
2461800000	Solvent Utilization; Miscellaneous Non-industrial: Commercial; Pesticide Application: All Processes; Total: All Solvent Types
2810030000	Miscellaneous Area Sources; Other Combustion; Structure Fires; Total

i. Architectural Coating

To estimate growth factors representing the future year to base year change in volume of architectural coatings consumed, Pechan developed the following equation by regressing national coating shipments over the period 1981-2001 against data for a number of potential explanatory variables:

$$y = b_0 + b_1 * x + b_2 * LAG(y) \quad \text{(Eq. 1)}$$

[6] Note that there may be other SCCs for which the final version of EGAS 5.0 will incorporate additional regression equations. Pechan will update the growth factor files to reflect the latest available information as to the list of SCCs for which the final EGAS 5.0 will utilize the approaches identified in this section.

where:

y	=	ratio of current year architectural coating shipments to base year shipments
b_0	=	-0.017
b_1	=	0.614
b_2	=	0.437
x	=	current year housing expenditures
$LAG(y)$	=	ratio of previous year's architectural coating shipments to base year shipments.

This equation is not incorporated into the beta EGAS 5.0 because the program currently does not support equations with lagged variables. In addition to the total volume of coatings used, it is important to reflect any projected change in the solvent content of these coatings because the emission activity for these SCCs is the amount of solvent emitted from these coatings. Therefore, Pechan recommended that EPA incorporate factors into EGAS 5.0 that reflect the projected future year architectural coating solvent content relative to base year solvent content (Pechan, 2004). Although these factors are not incorporated into the beta EGAS 5.0, they are expected to be included in the final EGAS 5.0. Therefore, Pechan obtained data representing the proportion of forecast year total and 2002 total architectural paints shipments that are solvent-based from the Freedonia Group, Inc. (Freedonia, 2002). Based on the available forecast information, Pechan applied a factor of 0.729 to the 2018 growth factor developed from the output of equation 1 for each State. The Freedonia data were reported for 1992 and each fifth year over the period 1996 to 2011. Pechan interpolated between the 2001 and 2006 values to obtain a 2002 value and used the 2011 value for 2018 in lieu of any forecast information beyond 2011.

ii. Commercial Pesticide Application

To estimate the amount of commercial pesticides applied, Pechan computed the following equation by regressing the national volume of active pesticide ingredients applied over the period 1980-1999 against data for a number of potential explanatory variables:

$$LOG(y) = b_0 + b_1 * LAG\,(LOG(y)) + b_2 * LOG(x) \quad \text{(Eq. 2)}$$

where:

$LOG(y)$	=	ratio of current year log of volume of active pesticide ingredients to base year log of volume of ingredients
b_0	=	-0.003
b_1	=	0.480
b_2	=	0.334
x	=	current year Agricultural Chemicals sector (SIC code 287) employment
$LAG(LOG(y))$	=	ratio of previous year's log of volume of active pesticide ingredients to base year's log of volume of ingredients.

This equation is not incorporated into the beta EGAS 5.0 because the program currently does not support equations with lagged variables. It is important to reflect any projected change in the solvent content of the pesticides. Therefore, Pechan recommended that EPA incorporate factors into EGAS 5.0 that reflect the ratio of future year volume of solvents per dollar of Agricultural Chemical sector shipments to base year volume of solvents for these shipments (Pechan, 2004). Although these factors are not incorporated into the beta EGAS 5.0, they are expected to be included in the final EGAS 5.0. Therefore, Pechan obtained data representing the proportion of forecast year and 2002 volume of solvents per dollar of Agricultural Chemicals sector shipments from the Freedonia Group, Inc. (Freedonia, 2003). Based on the available forecast information, Pechan applied a factor of 1.048 to the 2018 growth factor developed from the output of equation 2 for each State. Freedonia's solvent content data were reported for each fifth year over the period 1992 to 2012, including 2002. In lieu of any forecast information beyond 2012, Pechan used the 2012 value to represent 2018.

iii. Structure Fires

EPA acknowledges that the structure fires forecast methodology/data were not properly incorporated into the beta version of EGAS 5.0. Therefore, Pechan replaced the beta EGAS 5.0 structure fire growth factors to follow the two-step approach that Pechan developed for use in EGAS 5.0, and, which is expected to be incorporated into the final EGAS 5.0 (Pechan, 2004). This approach relies on an equation that relates the number of housing units to housing expenditures and factors representing the projected change in the number of structure fires per 10,000 housing units. For this study, Pechan applied a factor of 0.905 to the housing unit projections that represents the change in structure fires per 10,000 housing units between 2002 and 2018.

b. Revisions To Beta EGAS 5.0 Regression-Based Growth Factors

Because the EGAS 5.0 emission activity projection equations were developed using national historical data, it is unclear if the EGAS 5.0 equation growth rates will appear reasonable when incorporating State-level values into each equation. Therefore, Pechan reviewed the output for each State to identify potentially anomalous growth factors. Pechan selected growth factors of 2 and 0.2 to represent thresholds in determining suspect values. In cases where State-level values were deemed to be questionable, Pechan implemented one of two types of refinements, depending on the number of States for which the equation-based approach resulted in suspect growth rates. The following summarizes the two types of refinements that were applied.

The first refinement, which was used when the equation output appeared questionable for many States, was to use a combination of national and State REMI data. This approach first projects national growth factors up through 2009 by inputting <u>national</u> values of the independent variable in the emission activity equation. The 2009-2018 national growth rates were estimated using methods that were unique for each source category.[7] Pechan developed State-level growth factors by multiplying the national equation-based factors by ratios representing each State's

[7] Post-2009 growth factors were not projected using the equation-based approach because of concerns that the estimated national post-2009 growth rates appear to be unsustainable.

growth relative to National growth for the REMI indicator used in the regression equation. Section a below provides further details on this projection approach.

The second refinement, which was applied to a few specific States when the State-level equation output appeared reasonable in most cases, was to use the State-level output of the equation only up through either 2007 or 2009. The 2018 growth factors were estimated for these States by extrapolating each State's projected growth over the 2002 to 2007/9 timeframe using an exponential curve fitted to the data for this period. Further details on this refinement are provided in Section ii below.

i. National Equation-Based Growth Factors

For three source categories – Consumer/Commercial Solvents: All Federal Insecticide, Fungicide and Rodenticide Act (FIFRA) Related Products; Surface Coating: Miscellaneous Manufacturing; and Consumer/Commercial Solvents: All Coatings and Related Products, the use of State-level REMI forecasts in the nationally-derived emission activity estimation equations results in numerous anomalous growth rates. For these source categories, Pechan first utilized national REMI projections in the emission activity equations. Because of the dramatically higher growth/decline predicted after 2009, Pechan used the regression equation to directly develop national growth factors only through 2009.

Consumer/Commercial Solvents: All FIFRA Products

The 2009 national growth factor was held constant through 2018 for this category because the emission activity equation first predicted a continuation of the historical decline in activity for this category through 2009, then forecasted an increase in activity that was uncharacteristically large by 2018. Because of the uncertainty of the predicted post-2009 trend, Pechan held the 2018 national growth factor constant at 2009 levels. Pechan developed State-level growth factors for this category by multiplying the national growth factors by State/National growth factor ratios. These ratios were determined using State/National projections for the REMI indicator (population) that was included in the emission activity equation.

Surface Coating: Miscellaneous Manufacturing and Consumer/Commercial Solvents: All Coatings

To estimate national 2018 growth factors for each of these two categories, Pechan reduced each national post-2009 annual growth rate, as estimated by each emission estimation equation, by one-half. This adjustment factor was used because it resulted in post-2009 growth rates that approximated those predicted over the 2002-2009 period. Pechan developed State-level growth factors by multiplying the national growth factors by State/National growth factor ratios. These ratios were determined using State/National projections for the REMI indicators that were included in each regression equation (value added in Miscellaneous Manufacturing Industries sector and value added in Chemicals and Allied Products sector).

ii. State Equation-Based Growth Factor Changes

Sulfite Pulping

The use of State-level REMI forecasts in the nationally-derived Sulfite Pulping emission activity equation resulted in uncharacteristically large post-2009 growth rate changes in the District of Columbia. For DC, Pechan used the output of the regression equations up through 2009; 2018 growth factors were developed by extrapolation using an exponential curve fitted to the 2002-2009 growth factor projections.

Electronic and Other Electrical Surface Coating

For Iowa, the use of State-level REMI forecasts in the nationally-derived Electronic and Other Electrical emission activity equation resulted in unusually large post-2007 growth rate changes. For this State, Pechan utilized the State-level equation output to develop growth factors through 2007. The 2018 growth factor was developed for Iowa via extrapolation using an exponential curve fitted to the projected 2002-2007 Iowa growth factors.

c. Non-EGAS Data Sources

Because EGAS provides a *default* set of emission activity growth indicators, Pechan reviewed the availability of better projections sources where time and resources permitted. The following two sections describe specific areas where EGAS default information was replaced with projections from alternative data sources.

i. Population

EGAS is geographically defined by State, and so differences in growth within a State are not reflected in the EGAS default growth factors. Therefore, to account for differences in population projections within a State, Pechan obtained county-level population projections from each State in the CENRAP region and replaced the State-level EGAS population projections with these county-level population projections (Kansas, 2004; LPDC, 2003; MNPLAN, 2002; MO, 1999; ODOC, 2002; SLI, 2004; TXCDS, 2004; UALR, 2003; and UNE, 2002). Appendix Table C-1 presents the population projections complied for this effort.

ii. Other Data

Because of resource constraints, Pechan's research into potential alternative data sources focused on the EGAS growth surrogates that are applied to the highest-emitting point, nonpoint, and nonroad SCCs in the base year inventory for the CENRAP States.[8] Tables III-1 through III-5 in an earlier Pechan report present the top 10 SCCs responsible for the highest 2002 emissions in the CENRAP States for each of the following pollutants: NO_x, PM25-PRI, NH_3, SO_2, and VOC (Pechan, 2005). Based on this review, Pechan was able to identify alternative data sources that

[8]Note that this discussion only applies to nonroad SCCs that not included in the NONROAD model. Refinements to the NONROAD model default growth information are addressed in Section D.1.

were deemed to provide better emission activity surrogates for many of these SCCs. These surrogates are summarized in Table II-4. The following sections describe the rationale for the use of these non-EGAS growth surrogates for projecting emissions in the CENRAP States.

Oil and Gas Production Forecasts

Pechan used DOE's *Annual Energy Outlook* 2004 regional forecasts of onshore and offshore oil and gasoline production (DOE, 2004). From maps of the regions, the production values were allocated to the lower 48 continental States. New Mexico and Texas were the only States to belong to multiple onshore production regions. For these States, Pechan calculated the total production from all regions associated with each State. For SCC 2310000000, on and offshore drilling, the offshore area of the Pacific was added the onshore West Coast region and the offshore area of the Gulf was added to the on-shore region the Gulf Coast to develop growth factors for the States within the overlapping regions.

Historical Average Acres Prescribed Burned

Historical prescribed burning acreage data indicate that 2002 represented a year with uncharacteristically high levels of burning activity. Therefore, Pechan computed the average acreage burned in each State from data available over the period 1996 through 2003 (EPA, 2005). The 2018 growth factors were then developed for each State by computing the ratio of 2002 acreage to the average acreage over the 1996 to 2003 period.

Planted Crop Acreage Forecasts

Pechan obtained 2002 through 2013 national planted acreage projections for major crops from the USDA (ERS, 2004). Pechan then developed an estimated national 2018 planted acreage value via linear extrapolation of the 2002 through 2013 trend.

USDA Livestock Projections

Pechan obtained national livestock projections from USDA's "February 2004 Agricultural Baseline, Projection Tables to 2013" for beef cows, cattle, young chickens and turkeys (ERS, 2004). The USDA's 2002 to 2013 estimates were projected to 2018 using linear extrapolation. The USDA data for young chickens and turkey data were combined for use in projecting poultry SCC emissions activity.

Table II-4. Summary of Non-EGAS Growth Indicators Used For Highest-Emitting SCCs in CENRAP Region

SCC	SCC Description	Growth Indicator	
		EGAS5	This Study
2294000000	Mobile Sources; Paved Roads; All Paved Roads; Total: Fugitives	Population	Onroad VMT
2296000000	Mobile Sources; Unpaved Roads; All Unpaved Roads; Total: Fugitives	Population	Extrapolation of regional historical trend
2310000000	Industrial Processes; Oil and Gas Production: SIC 13; All Processes; Total: All Processes	SIC 13 constant $ output	AEO regional production forecast
2310001000	Industrial Processes; Oil and Gas Production: SIC 13; All Processes; On-shore; Total: All Processes	SIC 13 constant $ output	AEO regional production forecast
2310002000	Industrial Processes; Oil and Gas Production: SIC 13; All Processes; Off-shore; Total: All Processes	SIC 13 constant $ output	AEO regional production forecast
2801000003	Miscellaneous Area Sources; Agriculture Production - Crops; Agriculture - Crops; Tilling	Farm sector constant $ value added	USDA national crop projections
2810015000	Miscellaneous Area Sources; Other Combustion; Prescribed Burning for Forest Management; Total	No growth	Historical average (2002 levels were greater than average)
2805020002	Miscellaneous Area Sources; Agriculture Production - Livestock; Cattle and Calves Waste Emissions; Beef Cows	Farm sector constant $ value added	USDA national beef cow inventory projection
2805020004	Miscellaneous Area Sources; Agriculture Production - Livestock; Cattle and Calves Waste Emissions; Steers, Steer Calves, Bulls, and Bull Calves	Farm sector constant $ value added	USDA national cattle inventory projection
2805025000	Miscellaneous Area Sources; Agriculture Production - Livestock; Swine production composite; Not Elsewhere Classified (see also 28-05-039, -047, -053)	Farm sector constant $ value added	USDA national hog inventory projection
2805030000	Miscellaneous Area Sources; Agriculture Production - Livestock; Poultry Waste Emissions; Not Elsewhere Classified (see also 28-05-007, -008, -009)	Farm sector constant $ value added	USDA national turkey plus young chicken inventory projection
2805047100	Miscellaneous Area Sources; Agriculture Production - Livestock; Swine production - deep-pit house operations (unspecified animal age); Confinement	Farm sector constant $ value added	USDA national hog inventory projection
30202001	Industrial Processes; Food and Agriculture; Beef Cattle Feedlots; Feedlots: General	Farm sector constant $ value added	USDA national beef cow inventory projection

Onroad Vehicle Miles Traveled Projections

Pechan used onroad VMT projections to forecast paved road fugitive dust emissions activity. The VMT projections are discussed in Section E.1 of this report.

Extrapolation of Historical Unpaved Road VMT Trend

Unpaved road VMT for 1990 to 2002 were compiled for each of the CENRAP States, based on data used in EPA's National Emission Inventory. A review of the data indicated a disconnect between the 1995 and 1996 values and questionable State-level unpaved road VMT trends. In addition, data for Arkansas and Minnesota appeared questionable for multiple years. Therefore, Pechan concluded that the most reasonable approach would be to develop a single regional growth factor based on post-1995 unpaved road VMT data excluding data for Arkansas and Minnesota. First, Pechan summed the VMT estimates for each year across CENRAP States (excluding Arkansas, and Minnesota). Next, Pechan identified a best fit linear function from the 1996 to 2002 regional data and used that function to estimate 2018 unpaved road VMT in the CENRAP region. The 2002 to 2018 regional growth factor (0.813) was then applied to all of the CENRAP States.

Point Source NOx Cap in Texas Ozone Nonattainment Areas

To account for a point source NO_x emissions cap in certain Texas ozone nonattainment area counties, Pechan applied a no growth assumption (growth factor of 1.0) to all NO_x point sources in the following Texas counties: Brazoria, Chambers, Collin, Dallas, Denton, Fort Bend, Galveston, Hardin, Harris, Jefferson, Liberty, Montgomery, Orange, Tarrant, and Waller.

Integrated Planning Model

Pechan compiled a comprehensive set of growth factors for all base year EGU SCC records using EGAS 5.0. The EGAS 5.0 defaults are based on DOE's *Annual Energy Outlook* electric generation sector energy forecasts (DOE, 2004). For the final CENRAP modeling, it is anticipated that some, but not all, base year EGU SCC records will be projected using forecast information from IPM runs.

B. DEVELOPMENT OF CONTROL FACTORS FOR NON-EGU POINT SOURCES

This section describes control factor development for non-EGU point sources. This analysis focused on Federal, State, and local rules and regulations that are expected to reduce emissions or emission rates for criteria pollutants in the CENRAP States post-2002. After the control factor development is described, some examples of resulting emissions are provided as a point of reference.

1. State Controls

a. Texas

For developing control factors (expected emission reductions) for the non-EGU point source categories in Texas, it was recommended by Texas Commission on Environmental Quality (TCEQ) staff that the most recent Houston/Galveston Area (HGA) ozone episode modeling files be reviewed. Appropriate data are those listed in Chapter 3: Photochemical Modeling 2007 Future Base Case Summary of Controls Applied found on the TCEQ website (TCEQ, 2004). Separate files are posted according to the geographic area covered, and the applicable control programs. The non-EGU portion of this table is summarized below:

Geographic Area	Base Inventory	Controls Applied	File Name
Beaumont/Port Arthur	NEGU	Ch. 117 controls via Emission Factor Survey; assuming no VOC controls	control.2007.BPA.NEGU
Houston/Galveston	NEGU HRVOC Cap	2007 NO_x Cap Revised Speciation and Cap Cutoff Levels	control.HG_07NOxCap_NEGU control.new_hga_hrvoc_cap.to2n2_negu and then apply control.new_hga_hrvoc_cap.less20inharris
Dallas/Ft. Worth	NEGU	Ch. 117 controls via Emission Factor Survey; assuming no VOC controls	control.2007.dfw.negu
East Texas	Cement Kiln NO_x	Permit modifications	Already applied permit modifications to afs.MidloKilns._v5 via ellis_kilns.TIPI.00-07
	Agreed Orders and Consent Decree for East Texas	Specific reductions at ALCOA and Eastman	AgreedOrdersControlFactors00to07
West Texas	NEGU	None	None

i. Beaumont/Port Arthur (BPA)

The Beaumont/Port Arthur ozone nonattainment area includes Hardin, Jefferson, and Orange counties. TCEQ (2000a) expects that Tier 1 reductions in NO_x emissions from these three counties will be enough for Beaumont/Port Arthur to attain the 1-hour ozone standard.

The BPA.NEGU file lists the point sources in the Beaumont-Port Arthur ozone nonattainment area that have control factors applied for NO_x. Control factors were developed by facility and unit by the TCEQ by comparing survey results that established base year NO_x emission factors with Chapter 117 NO_x emission limits (which are by source category). The survey included all BPA NO_x sources with 25 tons per year or more of NO_x. Source-specific NO_x control factors range from 0.16 to 1.00 for affected sources.

ii. Houston/Galveston (HGA)

The Houston/Galveston ozone nonattainment area includes Brazoria, Chambers, Fort Bend, Galveston, Harris, Liberty, Montgomery, and Waller counties. On December 6, 2000, the TCEQ adopted a program for the trading of NO_x allowances in the HGA nonattainment area. The

trading of these allowances takes place under an area-wide cap. The program requires incremental reductions beginning in 2003 and continuing through 2007, when the full reductions of the program are to be achieved. The trading program is expected to provide as much flexibility in meeting these limits as possible.

The most recent HGA SIP revision is based on analysis to date showing that limiting emissions of ethylene, propylene, 1,3-butadiene, and butanes in conjunction with an 80 percent reduction in NO_x is equivalent in terms of air quality benefit to that resulting from a 90 percent point source NO_x reduction requirement.

The Control.HG_NOxCap_NEGU files for 2007 and 2010, when applied to estimate a control factor for 2018, yield a control factor of 0.45 (a 55 percent reduction). The control factor affects all non-EGU point source NO_x emissions in this nonattainment area.

There are also requirements for additional fugitive VOC emission reductions in Houston-Galveston. These include new rules to reduce emissions of highly reactive VOCs from four key industrial sources: fugitives, flares, process vents, and cooling towers. The highly reactive VOC rules are performance-based, emphasizing monitoring, record keeping, reporting, and enforcement, rather than establishing individual unit emission rates. After evaluation of how these rules were applied in the Houston SIP analysis, which involved adding highly reactive VOCs to the 2000 emission inventory and removing those HRVOC emissions in the future case, it was decided to not apply any VOC control factors to the 2002 VOC emissions in the 2018 emission projections.

iii. Dallas/Fort Worth

Appendix F of the Dallas/Fort Worth ozone nonattainment demonstration (TNRCC, 1999a) identifies NO_x control factors proposed for specific industrial boilers and engines and EGUs in that area. These unit-specific reductions will be applied to estimate 2018 NO_x emissions.

30 TAC 117, Subchapter 13 limits NO_x emissions from cement kilns in the Dallas/Fort Worth area. This rule establishes emission limits on the basis of pounds of NO_x per ton of clinker produced. These limits are based on the NO_x emissions averaged over each 30 consecutive day period (later changed to a 365 day period), and vary depending on the type of cement kiln. These NO_x emission limits by kiln type are as follows:

1. For each long wet kiln:
    a. In Bexar, Comal, Hays, and McLennan Counties, 6.0 lbs/ton of clinker produced
    b. In Ellis County, 4.0 lbs/ton
2. For each long dry kiln, 5.1 lbs/ton
3. For each preheater kiln, 3.8 lbs/ton
4. For each preheater-precalciner or precalciner kiln, 2.8 lbs/ton

These emission limits are expected to achieve a 30 percent reduction in cement kiln NO_x emissions.

Appendix F of the Dallas/Fort Worth ozone nonattainment demonstration (TNRCC, 1999a) identifies eleven cement kilns modeled as part of the proposed Dallas/Fort Worth NO_x emission reduction strategy. The level of NO_x controls required by TNRCC ranged by unit from 6 percent to 66 percent. These controls were applied on a unit-by-unit basis.

The DFW.NEGU file lists the point sources in the Dallas-Ft. Worth area that have control factors applied for NO_x. Control factors were developed by facility and unit by the TCEQ using the same emission factor survey and comparison with NO_x emission limit technique that was described above for Beaumont-Port Arthur. The survey included all DFW NO_x sources that reported 2 tons per year or more of NO_x. Source-specific control factors range from 0.13 to 1.00 for affected sources.

Agreed order control factors from the TCEQ were applied to simulate the effects of such orders on two facilities. A control factor of zero is applied to the Eastman plant (482030019), simulating the shutdown of this facility. NO_x control factors are applied to three boilers at the Alcoa (483310001) aluminum production facility.

Another TCEQ control factor file contains information about the future year criteria pollutant emissions for the cement kilns in Ellis County. These emission estimates were used to estimate appropriate growth and control factors for the 2018 emission forecasts for this area/source category.

b. Missouri

The fine grid counties in eastern Missouri are affected by EPA NO_x SIP Call requirements. The State of Missouri supplied information about unit-specific NO_x emission reductions for affected facilities. For non-EGUs, this included an 8 ton per ozone season NO_x emission limit applied to Anheuser Busch-Unit 6, a 9 ton per ozone season limit applied to Trigen-Unit 5, and a 36 ton per ozone season limit applied to Trigen-Unit 6.

c. Kansas

Rule 28-19-717 requires control of VOC emissions from commercial bakery ovens in Johnson and Wyandotte counties. This rule applies to bakery ovens with a potential to emit VOCs equal to or greater than 100 tons per year. Each commercial bakery oven subject to this regulation shall install and operate VOC emissions control devices for each bakery oven to achieve at least an 80 percent total removal efficiency on the combined VOC emissions of all baking ovens, calculated as the capture efficiency times the control device efficiency. Each bakery oven (Keebler Company) in these two counties with more than 100 tons per year of VOC emissions in 2002 had an 80 percent VOC control efficiency applied in the 2018 projections.

d. Louisiana

Point sources in the Baton Rouge nonattainment area and the nearby region of influence are affected by Chapter 22 NO_x control provisions. The provisions of this chapter apply to any

affected facility in the Baton Rouge nonattainment area (the entire parishes of Ascension, East Baton Rouge, Iberville, Livingston, and West Baton Rouge) and the Region of Influence (affected facilities in the attainment parishes of East Feliciana, Pointe Coupee, St. Helena, and West Feliciana). The provisions of this chapter apply during the ozone season (May 1 to September 30) of each year. Compliance is expected to occur as expeditiously as possible, but no later than May 1, 2005.

The effects of this NO_x regulation were included in the analysis by applying a 34 percent NO_x emission reduction to the 2002 non-EGU point source emissions in the greater Baton Rouge area. This control factor application is consistent with what was included in the most recent Houston-Galveston area modeling domain assessments by the TCEQ.

2. Federal Maximum Achievable Control Technology (MACT) Standards

Numerous MACT standards have been promulgated pursuant to Section 112 of Title I of the Clean Air Act, and are controlling emissions of hazardous air pollutants (HAPs) from stationary sources of air pollution. Many of the MACT standards are expected to produce associated VOC reductions, since many HAPs are also VOCs, so the emission projections need to capture the expected effects of post-2002 MACT standards.

Pechan performed the following steps to determine the MACT standards expected to have the greatest impact of VOC, NO_x, and PM emissions for the forecast year:

1. Identified the source categories and associated SCCs for each MACT standard having a post-2002 compliance date for existing sources.
2. Eliminated MACT categories that do not achieve significant VOC emission reductions.
3. VOC emission reduction estimates for the reciprocating internal combustion engine MACT category are based on information from EPA's Clean Air Interstate Rule technical support document (Alpine, 2004).
4. VOC emission reduction estimates for all other MACT categories are based on information found in the preamble to the final rule of each MACT Subpart as published in the *Federal Register*. Table II-5 lists those MACT categories for which VOC, NO_x, and/or PM emission reduction percentages could be estimated based on emission reduction information found in the preamble to each respective final rule.

3. Non-EGU Point Source Analysis Results

a. Houston Galveston Area (HGA)

Pechan's modeling of the NO_x emissions cap in the 8-county HGA applies a 55 percent NO_x emission reduction to the 2002 NO_x point source emissions. NO_x emissions in the HGA are expressed in annual tons. These annual tons and the equivalent ozone season daily (OSD) tons are listed below. Then, the right-most column below shows the comparable values from the TCEQ analysis for HGA.

Table II-5. Post-2002 MACT Standards and Expected VOC, NO_x, and PM Reductions

MACT Standard - Source Category	Code of Federal Regulations Subpart	Compliance Date (existing sources)	VOC (% Reduction)	NO_x (% Reduction)	Total PM (% Reduction)	Affected SCCs
Asphalt		5/1/2006	85			305001XX, 305002XX, 305050XX, 306011XX

NOTE: **Based on organic HAP emission reductions

	HGA Non-EGU NO_x Emissions		
	Annual Tons	**Daily Tons**	**TCEQ Analysis OSD Tons**
2002 Point Source NO_x	113,109	309.9	283
Post-cap NO_x	50,899	139.4	135

The TCEQ analysis OSD NO_x cap summary values above are for non-EGU 2000 NO_x and 2007 modeled NO_x (see Table 3.5-16 in their report). The above comparison indicates that the CENRAP NO_x modeling for HGA will be consistent with prior analyses by TCEQ for this area.

b. Beaumont-Port Arthur (BPA)

Pechan's modeling of the NO_x emissions cap in the 3-county BPA area applies NO_x control efficiencies based on an emission factor survey for the area. These results are summarized below.

	BPA Area Non-EGU NO_x Emissions		
	Annual Tons	**Daily Tons**	**TCEQ Analysis Daily Tons**
2002 Point Source NO_x	35,441	97.0	96.6
Post-cap NO_x	28,254	77.4	81.9

The TCEQ analysis OSD NO_x cap summary values above are for non-EGU 2000 NO_x OSD and 2007 modeled NO_x with growth and controls. The CENRAP non-EGU NO_x emissions in the 2002 point source file are about the same as the 2000 estimates on an OSD basis. However, the expected emission benefit of the non-EGU NO_x controls is greater than that modeled by TCEQ on both a percentage and an absolute tonnage basis.

c. Dallas Fort Worth (DFW)

Pechan's modeling of the NO_x emissions cap in the 4-county DFW area applies NO_x control efficiencies to certain sources based on an emission factor survey for the area. These results are summarized below.

	DFW Area Non-EGU NO_x Emissions		
	Annual Tons	**Daily Tons**	**TCEQ Analysis Daily Tons**
2002 Point Source NO_x	846	2.3	6.9
Post-cap NO_x	647	1.8	13.1

The TCEQ analysis OSD NO_x ton values listed above are for non-EGU 2000 NO_x OSD and 2007 modeled NO_x with growth and controls. The 2002 and post-cap NO_x tons listed for the DFW area only include sources affected by the NO_x control program, so these values are much lower than the TCEQ emissions, which include all non-EGU point source emissions in the area.

d. Baton Rouge

Pechan's modeling of the NO_x emissions cap in the greater Baton Rouge area applies a 34 percent NO_x emissions reduction to the 2002 NO_x point source emissions. These results are summarized below.

	Baton Rouge 9-Parish Area Non-EGU NO_x Emissions		
	Annual Tons	**Daily Tons**	**TCEQ Analysis Daily Tons**
2002 Point Source NO_x	74,847	205	630.9
Post-cap NO_x	49,399	135	586.2

The TCEQ analysis daily tons summary values above are for the entire State of Louisiana, and are for non-EGU 2000 NO_x and 2007 NO_x with growth and LDEQ SIP controls. Because the TCEQ summaries are for the entire State, the values are necessarily higher than those for the 9-parish area. Pechan estimates a 70 tpd NO_x reduction for the 9-parish NO_x control program. TCEQ estimates that the Statewide emission benefit of the LDEQ SIP controls is a 45 tpd reduction from 2000 levels, or a 61 tpd reduction from what the 2007 NO_x emissions would be expected to be without the Baton Rouge SIP controls.

C. DEVELOPMENT OF CONTROL FACTORS FOR AREA SOURCES

1. State Controls

Table II-6 summarizes regulations in the CENRAP States for which more stringent State requirements relative to Federal rules are in place for the mobile equipment repair and refinishing (MERR), architectural and industrial maintenance (AIM) coatings, consumer products and solvent cleaning area source VOC emission categories. For categories where more stringent rules for these categories are not found in the State regulations, “National Rule” is stated to refer to the applicable Federal requirements. The sections below describe how the information from these rules were used to develop control efficiencies. Table II-7 summarizes the final control efficiencies that were used to model these rules, and the counties and SCCs where these rules were applied.

Stage II, or at-the-pump, refueling control programs are in place in three States in the CENRAP region—Louisiana, Missouri, and Texas. Although these programs may have been in place prior to 2002, these controls are included here because the phase-in of the onboard vapor recovery systems controls changes the overall refueling control efficiency of Stage II programs.

Table II-6. VOC Solvent Rule Summary

SCCs	2465000000	2401001000	2415360000, 2415300000, 2415230000, 2415200000	2401005000

Texas	Chapter 115.612 establishes control requirements effective in February 2004 for automotive windshield washer fluid. No person shall sell, supply, offer for sale, distribute, or manufacture for use in Texas any automotive windshield washer fluid containing VOCs in excess of 23.5% by weight.	Rule 115.420 applies to surface coating processes.	Degreasing processes in the Beaumont/Port Arthur, Dallas/Ft. Worth, and Houston/Galveston areas and in Gregg, Nueces, Victoria, Bexar, Comal, Guadalupe, Wilson, Bastrop, Caldwell, Hays, Travis, and Williamson counties have VOC control requirements via Chapter 115.412 for cold solvent cleaning and open-top vapor or conveyorized degreasers. The cold solvent cleaner requirement is equivalent to a VOC reduction efficiency of 65 percent or greater. The open-top vapor or conveyorized degreaser requirement is equivalent to a VOC reduction efficiency of 85 percent or greater.	Rule 115.422 control requirements apply in Beaumont/Port Arthur, Dallas/Fort Worth, El Paso, and Houston/Galveston. Vehicle refinishing operations shall minimize VOC emissions during equipment cleanup via enclosed containers for washing, rinsing, and draining, keeping wash solvents in an enclosed reservoir, and waste solvents and other cleaning materials in closed containers. Coating application equipment shall have a transfer efficiency of at least 65 percent.	

Table II-7. VOC Solvent Controls As Modeled

Counties	Pollutant	Control Efficiency* (%)	SCC	Description
KS: Johnson, Wyandotte	VOC	66	2415000000	Solvent Utilization: Degreasing: All Processes/All Industries
TX: Dallas, El Paso, Galveston, Hardin, Harris, Jefferson, Tarrant	VOC	35	2401005000	Auto Refinishing: SIC 7532
TX: Bastrop, Bexar, Caldwell, Comal, Gregg, Guadalupe, Hays, Nueces, Travis, Victoria, Williamson, Wilson	VOC	83	2415105000	Furniture and Fixtures (SIC 25): Open Top Degreasing

			2415145000	Miscellaneous Manufacturing (SIC 39): Open Top Degreasing
TX: Statewide	VOC	17	2460400000	Solvent Utilization: Miscellaneous Non-industrial: Consumer and Commercial: All Automotive Aftermarket Products

*These control efficiencies are all applied with a rule penetration of 100 percent and a rule effectiveness of 100 percent.

a. Kansas

i. Solvent Cleaning Operations

Kansas Rule 28-19-714 contains a 1.0 mm Hg maximum vapor pressure requirement for solvent cleaning operations, effective September 2002. Based on an evaluation of the Ozone Transport Commission (OTC) model rule for this source category, a 1.0 mm Hg at 68°F maximum VOC vapor pressure requirement leads to an estimated 66 percent reduction in VOC emissions relative to the national rule for cold cleaners and vapor degreasers (Pechan, 2001). The Kansas rule also includes a higher (5.0 mm Hg at 68°F) maximum vapor pressure requirement for the cleaning of carburetors, but this difference may not be significant relative to the OTC rule. Conveyorized degreasers are required to achieve an overall VOC control efficiency of 65 percent or greater; however, the Kansas rule does not appear to include any additional requirements relative to the national rule (other than the maximum vapor pressure requirements). Therefore, a 66 percent post-2002 VOC control efficiency was applied in Johnson and Wyandotte Counties, based on data from the OTC model rule.

b. Missouri

i. Solvent Cleaning Operations

Based on Pechan's review of Missouri's regulations, solvent cleaning regulations applicable to the Kansas City and St. Louis metropolitan areas appear to be more stringent than the national rule; however, these rules became effective before 2002. Therefore, no additional solvent controls were applied in Missouri.

ii. Stage II Refueling Controls

Stage II controls are required in the city of St. Louis and the following St. Louis area counties: Franklin County, Jefferson County, St. Charles County, and St. Louis County. This is required under 10 CSR 10-5.220 "Control of Petroleum Liquid Storage, Loading and Transfer." This regulation requires that gasoline stations with a minimum monthly throughput of 10,000 gallons of gasoline are required to maintain a 95 percent efficiency of total capture and emission reduction. These gasoline station owners are required to comply with the Missouri Performance Evaluation Test Procedures beginning in 1998.

c. Louisiana

i. Solvent Cleaning Operations

Title 33, Part III, Section 2125 specifies additional operational requirements for open top vapor degreasers not found in EPA's 1977 control techniques guideline (CTG). One requirement of the Louisiana Code specifies a minimum 85 percent VOC reduction efficiency for open top vapor degreasers not found in the CTG. Section 2125 was last amended in April 2004.

ii. Stage II Refueling Controls

A Stage II control program is in place in the following parishes in Louisiana: Ascension, East Baton Rouge, Iberville, Livingston, Pointe Coupee, and West Baton Rouge. The Stage II controls are required to attain a minimum of 95 percent gasoline vapor control efficiency at stations with a minimum throughput of 10,000 gallons of gasoline per month. This rule is under Title 33, Part III, Section 2132 "Stage II Vapor Recovery Systems for Control of Vehicle Refueling Emissions at Gasoline Dispensing Facilities." Compliance with these regulations was first required in 1993.

d. Texas

i. Cold Cleaners

The 1977 CTG for cold solvent cleaners is estimated to achieve VOC emission reductions of between 55 and 69 percent relative to 1977 baseline (uncontrolled) levels (Pechan, 2002). Texas rule 115.412 is equivalent to VOC emission reductions of at least 65 percent relative to uncontrolled levels. There do not appear to be any significant differences between the Texas rule

and the CTG, and therefore no additional VOC reductions were applied to the 2002 Texas inventory for cold cleaners.

ii. Open-top Vapor or Conveyorized Degreasers

The national rule for vapor degreasing is estimated to achieve VOC emission reductions of between 10 and 15 percent (Pechan, 2002). The Texas rule 115.412 requires VOC emission reductions of at least 85 percent from these sources for the following counties: Bastrop, Bexar, Caldwell, Comal, Gregg, Guadalupe, Hays, Nueces, Travis, Victoria, Williamson, and Wilson. Assuming that the baseline 2002 vapor degreasing emissions include a 10 percent reduction from the national rule and that a total control of 85 percent would be applied to comply with the Texas rule, the incremental reduction from the Texas rule, relative to the 2002 emissions, would be 83 percent. This rule became effective in December 2004.

iii. Mobile Equipment Repair and Refinishing

Texas rule 115.422 requires that coating application equipment shall have a transfer efficiency of at least 65 percent and requires the use of high volume low pressure (HVLP) spray guns. This rule applies in the following counties: Dallas, El Paso, Galveston, Hardin, Harris, Jefferson, and Tarrant. Based on an evaluation of the OTC model rule for this source category, the use of "high transfer efficiency" HVLP guns is estimated to achieve a 35 percent VOC emission reduction relative to the national rule (Pechan, 2001). Spray gun controls are estimated to contribute an additional 3 percent VOC emission reduction. However, the Texas rule contains a less stringent requirement for the enclosure of spray guns and related parts. Therefore, a 35 percent post-2002 VOC control efficiency incremental to the national rule was applied in the counties listed above to account for this rule. This rule became effective in May 2002.

iv. Consumer Products

The national rule limits the VOC content of windshield wiper fluid to 35 percent by weight (effective December 1998). The Texas rule 115.612 limits the VOC content to 23.5 percent by weight. This represents a 33 percent reduction in the VOC content (and as a result, emissions) from the 2002 baseline. A single SCC includes all "auto aftermarket products". Therefore, an assumption must be made as to what fraction of emissions from auto aftermarket products can be attributed to auto wiper fluid. An engineering estimate of 50 percent was applied, based on the assumption that the other major VOC-emitting auto aftermarket products (waxes, polishes and cleaning products) are likely consumed in lesser quantities by volume than windshield wiper fluid. Thus, the reduction applied to VOC emissions from the SCC representing auto aftermarket products was 17 percent. This rule became effective in February 2004.

v. Portable Fuel Containers

Texas has a portable fuel container rule (Statewide). In TCEQ analyses, this has been modeled as a reduction in evaporative VOC emissions using lawn and garden equipment SCCs within EPA's NONROAD model. See the Nonroad section of this chapter for information about how the rule effects were incorporated in the analysis.

vi. Stage II Refueling Controls

Stage II refueling controls are required in the following Texas counties: Brazoria, Chambers, Collin, Dallas, Denton, El Paso, Fort Bend, Galveston, Hardin, Harris, Jefferson, Liberty, Montgomery, Orange, Tarrant, and Waller. This is regulated by the TCEQ Chapter 115, Sections 240 through 249 "Control of Vehicle Refueling Emissions (Stage II) at Motor Vehicle Fuel Dispensing Facilities." This regulation requires that gasoline stations with a minimum monthly throughput of 10,000 gallons of gasoline are required to have installed an approved Stage II vapor recovery system which is certified to reduce VOC emissions to the atmosphere by at least 95 percent. Annual inspections are required and the program began in 1992.

vii. Gas-fired Water Heaters, Small Boilers, and Process Heaters

A Statewide rule, adopted as part of the April 2000 Dallas/Forth Worth SIP revision, reduces NO_x emissions from new natural gas-fired water heaters, small boilers, and process heaters sold and installed in Texas beginning in 2002. The rule applies to each new water heater, boiler, or process heater with a maximum rated capacity of up to 2.0 million British thermal units per hour. This is Rule 117.461. It should be noted that this control on natural gas-fired water heaters may be overturned by the SB 473 prohibition on regulating water heater emissions.

To simulate the effects of this rule in 2018, the following factors were applied Statewide in Texas.

SCC	NO_x Control Efficiency	Rule Penetration	Rule Effectiveness
2103006000	75%	80%	100%
2104006000	75%	80%	100%

2. Federal Controls

a. Residential Wood Combustion

For this analysis, a 20 year estimated lifetime for woodstoves and fireplace inserts was used along with the SCC-specific growth factors, and emission factor ratios by SCC, to account for the replacement of retired woodstoves that emit at pre-new source performance standard (NSPS) levels, with new catalyst-equipped wood burning equipment. This was done using an equation to estimate equipment turnover for a situation with a 4 percent per year retirement rate, and the SCC-specific growth factors. Emission factor ratios are pollutant-specific. The growth and retirement equation was used to estimate the relationship between base year (2002) emissions and 2018 emissions by SCC and pollutant.

Then, this relationship was used to estimate the control efficiency that would have to be applied along with the growth factor to yield the appropriate future year emission value. SCCs for controlled woodstoves and fireplace inserts have no control efficiency applied. Their 2018 emissions will change in proportion to the growth rate. Table II-8 displays the various residential woodstove and fireplace area source SCCs that are used in the CENRAP State emission inventories and the associated 2018 control factors used in this analysis.

Table II-8. Residential Wood Combustion Control Factors for CENRAP States

SCC	Description	Growth Factor 2002 to 2018	Pollutant	CF*	2018 Ratio of Controlled/ Uncontrolled Emissions	2018 Control Factor (Emission Reduc. %)

NOTE: *The ratio between the emission factor for a certified-catalyst equipped woodstove/fireplace insert and for an uncontrolled unit.

b. Onboard Vapor Recovery Systems

The control efficiency from refueling onroad vehicles will be greater in 2018 than in 2002 due to vehicle turnover and the Federal requirement for onboard vapor recovery systems in onroad vehicles. Percentage reductions in VOC emissions from this control measure in 2018, relative to 2002, were calculated using a sampling of MOBILE6 runs, including the effect of Stage II programs where they are in place. These resulting reduction factors were included in the area source sector control files.

D. DEVELOPMENT OF NONROAD 2018 EMISSION INVENTORY

Pechan estimated NONROAD model mass emissions for 2018 for all CENRAP States using EPA's NONROAD2004 model (EPA, 2004a). Pechan developed nonroad option files to reflect season-specific inputs that applied to an entire State or group of counties. These runs also incorporated revised activity, seasonal allocation, and county allocation files developed by Sonoma Technology, Inc. (STI) to improve the recreational marine component of the 2002 base year NONROAD inventory (STI, 2004).

Pechan ran NONROAD for four scenarios: 1) typical January weekday (JanWD); 2) typical January weekend day (JanWE); 3) typical July weekday (JulWD); and 4) typical July weekend day (JulWE). The January runs represented average daily emissions for the time period October 1 through April 30, and the July runs represented average daily emissions for the time period May 1 through September 30. Annual emissions were estimated using these daily results as input to the formula below:

(JanWD x 152 days) + (JanWE x 60 days) + (JulWD x 109 days) + (JulWE x 44 days) = Annual Average Emissions

In Table II-9, the default Statewide temperatures and Reid vapor pressure (RVP) values used are listed for each model scenario. Pechan also accounted for local fuel-related programs that would affect NONROAD model engine emissions. A listing of the areas with county-specific fuel programs are presented in Tables II-10 through II-13. In addition, the characteristics or input values needed to model these programs in NONROAD are presented. Table II-10 provides a list of those areas that have year-round Stage II programs in place. Tables II-11 and II-12 show the summer season RVP values assumed for areas with reformulated gasoline and low RVP programs, as well as year-round oxygenated fuel programs that are part of RFG programs. Table II-13 presents the weight percent oxygen (O_2) levels used for the 2018 runs. Iowa, Minnesota, and El Paso County, Texas are the only areas with official oxygenated fuel programs. For the remaining areas, it was established that some blending of ethanol into their fuel is occurring, even though no regulatory requirement is in effect (STI, 2004). The 2018 diesel fuel sulfur values reflect the requirements of the Clean Air Diesel Rule that all nonroad diesel fuel meet 15 parts per million sulfur content by the year 2015. Per the requirements of the Tier 2 and gasoline sulfur rulemaking, the gasoline sulfur levels were also revised to 30 parts per million.

1. Growth

Growth factors in NONROAD2004 are based on national, historical changes in fuel-specific equipment populations. Pechan has concerns about using growth rates that vary significantly from the model growth rates without fully evaluating the impact the revised growth rates may have on other related activity variables such as median life and scrappage rates. Pechan did, however, reflect State differences in growth rates by adjusting the NONROAD model growth rates for several significant nonroad categories, as identified in CENRAP's 2002 base year NONROAD model inventory (STI, 2004). These adjustments were made using State-level growth rates based on surrogate socioeconomic indicators believed to correlate with activity for each category. These data are available from the REMI model, and are incorporated into EGAS (Houyoux, 2004). The proposed methodology for making these adjustments was first documented in a technical memorandum prepared for CENRAP (Pechan, 2005). The NONROAD priority categories, along with the socioeconomic indicator used to adjust the national growth rate for each category, are listed in Table II-14. Note that employment and value added data are available from REMI for the Agricultural Production sector (SIC 01, 02). This is expected to be a suitable surrogate for the growth in farm equipment, but growth rates for these variables were not calculated separately in REMI for each State, and are reported as the same value for all States. As such, Pechan used *Output in Agricultural Services* (SIC 07) as a surrogate indicator for farm equipment growth.

Table II-15 lists the NONROAD national growth factor value for 2018 (relative to 2002 base year) for each of the priority categories. Unlike other nonroad categories, separate growth rates are included in NONROAD for some of the specific recreational equipment applications, such as ATVs and Off-Highway Motorcycles. Table II-16 lists the 2018 growth factors for each chosen REMI surrogate indicator. Values are presented for each CENRAP State, as well as the nation. The general equation used to make this adjustment is shown below, along with an example of this calculation for gasoline lawn and garden equipment:

$$NRDGR_{ST} = NRDGR_{NAT} \times (REMIGR_{ST}/REMIGR_{NAT})$$

Table II-14. NONROAD Model Priority Growth Categories and REMI Data for Adjusting National NONROAD Growth Rates

NOTE: [1]Growth factor values calculated relative to base year 2002.

where:

$NRDGR_{ST}$	=	Revised NONROAD State-level Growth Rate
$NRDGR_{NAT}$	=	Base NONROAD National Growth Rate
$REMIGR_{ST}$	=	State REMI Growth Rate
$REMIGR_{NAT}$	=	National REMI Growth Rate

The revised growth rate for gasoline lawn and garden equipment in Oklahoma is calculated as follows:

$$NRDGR_{ST} = 1.337 \times (1.253 \div 1.218)$$
$$= 1.374$$

Table II-17 shows the adjusted 2018 growth factors calculated for all CENRAP States for all priority equipment categories, and compares these values to the NONROAD model default growth factor values.

Pechan prepared a revised NATION.GRW file for use in the NONROAD model. Once 2002-based growth rates were calculated, Pechan normalized these rates to reflect the 2002 year value in the NATION.GRW file. Since this year was not reported for most category codes, these 2002 data were calculated using linear interpolation of values reported for the most recent prior year and closest future year. Pechan then incorporated 2018 data for each of the appropriate indicator codes for all CENRAP States. State-specific records for historic years prior to 2002 were also added (since base year population values for most equipment types are for 1996 or 1998) using the same values as the national-level indicators.

2. Controls

EPA's NONROAD2004 model incorporates the effects of most final Federal standards, including the Tier 4 diesel engine standards and the exhaust emission standards for large spark-ignition (S-I) engines, diesel marine, and land-based recreational engines. The only remaining federal standards not modeled by NONROAD2004 include permeation and evaporative emission standards for gasoline recreational and large S-I engines, respectively. The evaporative standards for recreational equipment only affect permeation emissions, which are not currently included in NONROAD2004. These standards do not affect any other evaporative emission components in the model (i.e., diurnal or refueling). Therefore, Pechan did not model the recreational equipment permeation emission standards. Pechan developed an estimate of the emission reductions due to the large S-I standard to apply to the affected SCCs as a post-processing adjustment, which is discussed below.

For the large S-I evaporative standards, Pechan obtained overall emission reduction information from the Large S-I Regulatory Support Document (EPA, 2002). Using large S-I evaporative base and control case future year inventories, emission reductions were estimated for 2018. These emission reductions vary by evaporative component, but for this analysis Pechan summed the emissions across all components to estimate emission reductions for all evaporative

Table II-17. Adjusted 2018 Growth Factors for Nonroad Priority Equipment Categories

State FIPS	State Name	NONROAD Growth Factor[1]	Adjusted Growth Factor[1]	Percent Difference

NOTE: [1]Growth factor values calculated relative to base year 2002.

emissions combined, as well as crankcase emissions. Large S-I evaporative emission reductions for 2018 were estimated to be 78.1 percent.

Pechan calculated two rule penetration adjustments to account for the fraction of the SCC-level emissions that are affected by the rule. Since the rule only affects large S-I engines greater than 25 horsepower, the first adjustment was developed to reflect that fraction of the activity associated with these larger engines. This was estimated using 2002 national gasoline consumption results by horsepower and equipment category from NONROAD2004. As a simplifying assumption, we used the 2002 rule penetration value for 2018 and for all applications within a category, though this is likely to vary by year and application. Table II-18 provides a summary of the horsepower-related rule penetration values by equipment category. A second rule penetration adjustment by SCC was also developed to account for that fraction of the SCC-level emissions associated with evaporative VOC relative to the total VOC emissions (i.e., exhaust plus evaporative). Final emission reductions by SCC are presented in Table II-19. These emission reductions were applied directly to the SCC-level output from the NONROAD model as a post-processing step.

The following equation shows an example of how overall adjusted emission reductions were estimated for 4-stroke industrial forklifts in 2018:

$$ER_{ADJ} = RP_{hp} \ x \ RP_{evap} \ x \ ER$$

Table II-18. Horsepower-Related Rule Penetration Values by Category for Large S-I Evaporative Standards

Fuel Type	Classification	Rule Penetration

where:

ER_{ADJ} = adjusted emission reduction accounting for rule penetration
RP_{hp} = rule penetration for affected horsepower fraction
RP_{evap} = rule penetration for evaporative fraction of total VOC emissions
ER = evaporative emission reduction for affected engines

$$\begin{aligned} ER_{ADJ} &= 0.590 \times 0.529 \times 0.781 \\ &= 0.244 \\ &= 24.4 \text{ percent} \end{aligned}$$

a. State Controls

In addition to Federal controls, Pechan accounted for regulations in Texas that control nonroad refueling spillage emissions from use of portable fuel containers. Similar to the large S-I evaporative standard modeling discussed above, Pechan calculated two rule penetration adjustments accounting for the appropriate fraction of the SCC-level emissions affected by the rule. The first adjustment was developed to reflect that fraction of the SCC emissions associated with equipment fueled with a portable fuel container. Nonroad equipment refueled by a portable container are generally smaller horsepower engines than those refueled at service stations. A second rule penetration adjustment by SCC was also developed to account for that fraction of the SCC-level emissions associated with evaporative spillage VOC relative to the total VOC emissions (i.e., exhaust plus evaporative). These adjustments were both estimated using 2002 national evaporative VOC emissions data by horsepower, equipment category, and evaporative component, from NONROAD2004. Control efficiency was assumed to be 100 percent, and full equipment turnover of gas cans should be achieved by 2018.

The final emission reductions by SCC are presented in Table II-20. These emission reductions were applied directly to the appropriate SCCs as a post-processing step for all counties in Texas.

3. Non-NONROAD Model

Pechan compiled control information for commercial marine vessels and locomotives. Standards affecting these categories are Federal standards that affect all areas of the nation. No additional local controls were modeled in the CENRAP region for these categories.

In 2003, EPA proposed aircraft engine NO_x emission standards that will bring U.S. aircraft standards into alignment with standards developed by the International Civil Aviation Organization. EPA did not prepare emission reduction estimates for these standards because any such reductions would be modest (e.g., 94 percent of aircraft engines are currently meeting or exceeding these standards). Therefore, Pechan did not account for emission reductions from these standards for this analysis.

a. Locomotives

Emission reduction impacts of the Federal locomotive engine standards are available in an EPA Regulatory Support Document (EPA, 1998). This document contains emission reduction information specific to Class I Operations, Class II/III Operations, Passenger Trains (Amtrak and Commuter Lines), and Switch (Yard) Locomotives. Year-specific percentage reduction estimates for select pollutants are available for each locomotive sector for each year over the 1999-2040 period. These emission reductions reflect the control technology efficiencies, as well as the expected rule penetration for the years of interest. Rule effectiveness was assumed to be 100 percent.

In addition, overall SO_2, PM_{10}, and $PM_{2.5}$ emission reductions associated with decreases in the diesel fuel sulfur content were also included. These were estimated from future base case and control case locomotive emission inventories prepared for EPA's regulatory impact analysis (RIA) for the Clean Air Diesel Rule (EPA, 2004). In the case of PM, since exhaust PM standards already apply to locomotives, a combined emission reduction was calculated for each future year that accounted for both the exhaust standards and reductions in PM sulfate due to the fuel sulfur limits. Table II-21 presents the 2018 emission reductions that apply to locomotive SCC emissions.

b. Commercial Marine Vessels

EPA has promulgated two sets of commercial marine vessel regulations: a regulation setting Category 1 and 2 marine diesel engine standards and a regulation setting Category 3 marine diesel engine standards. Category 1 marine diesel engines are defined as engines of greater than 37 kilowatts but with a per-cylinder displacement of 5 liters/cylinder or less. Category 2 marine diesel engines cover engines of 5 to 30 liters/cylinder, and Category 3 marine diesel engines include the remaining, very large, engines. For this analysis, overall emission reductions were estimated for each projection year of interest using information from the regulatory support documents prepared for these rulemakings (EPA, 1999; EPA, 2003). In addition to the EPA standards, beginning in 2000, marine diesel engines greater than or equal to 130 kilowatts are subject to an international NO_x emissions treaty (MARPOL) developed by the International Maritime Organization. The emission reductions reflect both the MARPOL and EPA standards.

Because the reductions vary by category of vessel, assumptions were made concerning the characterization of engines associated with diesel commercial marine vessel SCCs included in the base year inventory. For SCC 2280002100 (Marine Vessels, Commercial Diesel Port emissions), Category 2 engines were assumed. For SCC 2280002200 (Marine Vessels, Commercial Diesel Underway emissions), Category 3 engines were assumed.

Table II-21. 2018 Emission Reductions and Control Information for Federal Rail Standards[1]

2285000000	Railroad Equipment All Fuels Total	VOC	23.6	47	100	50.2
2285002000	Railroad Equipment Diesel Total	VOC	23.6	47	100	50.2
2285002006	Railroad Equipment Diesel Line Haul Locomotives: Class I Operations	VOC	27	47	100	57.4
2285002008	Railroad Equipment Diesel Line Haul Locomotives: Passenger Trains (Amtrak)	VOC	26	47	100	55.3
2285002009	Railroad Equipment Diesel Line Haul Locomotives: Commuter Lines	VOC	26	47	100	55.3
2285002010	Railroad Equipment Diesel Yard Locomotives	VOC	10	50	100	20

NOTE: [1]Values for CE, RE, and RP for PM10 and PM25 were not estimated since these values account for PM reductions due to both exhaust and fuel sulfur standards.

Similar to locomotives, overall SO_2, PM_{10} and $PM_{2.5}$ emission reductions associated with decreases in the diesel fuel sulfur content were also included based on information in EPA's RIA for the Clean Air Diesel Rule (EPA, 2004b). See Table II-22 for the 2018 emission reductions that apply to commercial marine vessel SCC emissions.

E. DEVELOPMENT OF ONROAD DATA

For the onroad projections in the CENRAP air quality modeling, Pechan provided a set of VMT growth factors in SMOKE format, along with SMOKE-formatted MOBILE6 input files. The MOBILE6 input files incorporate any Federal, State, or local control program information. Thus, control factors or emission reduction percentages are not explicitly provided for this sector, but rather are incorporated in the MOBILE6 modeling. The development of the VMT growth factors and the MOBILE6 input files are discussed below. Once VMT growth factors were calculated for all of the CENRAP States, the growth factors were multiplied by the CENRAP base year 2002 VMT data to calculate 2018 VMT. The projected 2018 VMT by county and SCC (vehicle type and roadway type) were then provided in a SMOKE-formatted file, along with the corresponding average vehicle speed for that county/SCC combination. These speed inputs are the same as those used in the 2002 CENRAP base case—no updates were made to the modeled speeds.

1. VMT Growth

a. Default VMT Growth Methodology

As indicated in the Methods Document, Pechan's proposed default VMT growth methodology was to use EGAS VMT growth factors when more specific data were not supplied by the State or local agencies. However, when attempting to prepare the EGAS VMT growth factors using the beta version of EGAS 5, Pechan encountered a bug in the EGAS code that prevented data from being output for the onroad mobile SCCs. As an alternative (but similar) methodology, Pechan developed a set of 2002 to 2018 VMT growth factors using the same methodology used by EPA in their CAIR rule analysis that had originally been developed for EPA's draft Section 812 second prospective analysis (Mullen and Neumann, 2004).

The VMT projections account for vehicle class-specific growth factors and population growth factors. The data used for the vehicle class-specific growth factors are vehicle category-specific 2002 VMT and VMT projections to 2018, both at the national level, for the following three vehicle classes: 1) Light-duty vehicles (under 8,500 lbs); 2) Commercial light trucks (between 8,500 and 10,000 lbs); and 3) Freight trucks (greater than 10,000 lbs). These national VMT projections were obtained from the 2005 Annual Energy Outlook (DOE, 2005).

The national 2002 VMT and the 2018 VMT projections were allocated to the MOBILE6 vehicle categories using the default MOBILE6 VMT fractions by vehicle type in 2002 and 2018. Overall vehicle-specific growth factors were then calculated by multiplying the ratio of the 2018 to 2002 VMT at the MOBILE6 vehicle type level.

Table II-22. 2018 Emission Reductions and Control Information for Federal Diesel Commercial Marine Standards

SCC	SCC Description	Pollutant	2018 Emission Reduction, %	2018 Control Efficiency	2018 Rule Effectiveness	2018 Rule Penetration
2280002100	Marine Vessels, Commercial Diesel Port emissions	PM25-PRI	12.14	12.1	100	100
2280002100	Marine Vessels, Commercial Diesel Port emissions	PM10-PRI	12.14	12.1	100	100
2280002100	Marine Vessels, Commercial Diesel Port emissions	SO2	97.58	97.6	100	100
2280002100	Marine Vessels, Commercial Diesel Port emissions	NOX	20.46	43.7	100	46.8
2280002200	Marine Vessels, Commercial Diesel Underway emissions	PM25-PRI	12.14	12.1	100	100
2280002200	Marine Vessels, Commercial Diesel Underway emissions	PM10-PRI	12.14	12.1	100	100
2280002200	Marine Vessels, Commercial Diesel Underway emissions	SO2	97.58	97.6	100	100
2280002200	Marine Vessels, Commercial Diesel Underway emissions	NOX	14.88	43.2	100	34.4

Different levels of population growth throughout the CENRAP States were accounted for by calculating the ratio of county level population growth to national population growth. The population estimates used in these calculations were the EGAS population projections derived from Census population estimates and the REMI demographic/migration module which forecasts regional population change (REMI, 1997).

These resulting growth factors were then multiplied by the CENRAP 2002 VMT data at the county/roadway type/vehicle type level of detail to obtain projected 2018 VMT data. This is illustrated in the following equation:

$$VMT18_{C,V,R} = VMT02_{,C,V,R} * (VMT_{EIA18,V} / VMT_{EIA02,V}) * [(POP_{18,C}/POP02_{,C})/(POP_{18,US}/POP_{02,US})]$$

where:

$VMT18_{C,V,R}$	=	2018 projected VMT for county *C*, vehicle type *V*, road type *R* (million miles)
$VMT02_{C,V,R}$	=	2002 CENRAP VMT for county *C*, vehicle type *V*, road type *R* (million miles)
$VMT_{EIA20,\ \ V}$	=	2020 EIA-based VMT projection for vehicle type *V* (billion miles)
$VMT_{EIA99,V}$	=	1999 EIA-based VMT for vehicle type *V* (billion miles)
$POP_{20,C}$	=	2020 EGAS 4.0 population of county *C*
$POP_{99,C}$	=	1999 EGAS 4.0 population of county *C*
$POP_{20,US}$	=	2020 EGAS 4.0 population of *US*
$POP_{99,US}$	=	1999 EGAS 4.0 population of *US*

It should be noted that this equation does not specifically account for varying growth rates by functional roadway class. Our research in 2003 did not reveal a consistent national basis on which to make roadway-class-specific projections.

b. State or Local VMT Growth Methodology

Several State and local agencies within the CENRAP States provided data to be used in projecting VMT growth for that State or local area. Early in this project, Pechan asked the CENRAP emission inventory contacts for information on appropriate contacts from their State Departments of Transportation and from the major metropolitan planning organizations in their State. Pechan then inquired of these contacts whether they had developed their own VMT growth projections, and if so, the VMT growth data and will request any available documentation on the development of these growth factors and the growth factors themselves so that these growth factors would be applied correctly in the CENRAP projections. Responses to this request were provided by Arkansas, Iowa, Minnesota, Missouri, Nebraksa, and Oklahoma. However, the VMT projection data provided by Arkansas and Missouri were for 2003 only, and the VMT projection data provided by Nebraska were to 2009 only. Neither of these projections were considered sufficient for use in projecting VMT to 2018, so these data were discarded. Within the resources available, Pechan also attempted to locate publicly available projected VMT data for major cities within the CENRAP States that were not included in the State-

provided VMT projection data and was able to obtain projected VMT information for several cities in Texas. The non-default VMT projection data used are described below.

i. Iowa

The Des Moines Area Metropolitan Planning Organization (MPO) provided projected VMT data for four counties in the Des Moines area: Dallas, Madison, Polk, and Warren. For each of these counties, daily link-level VMT data were provided for the years 2000, 2005, 2010, 2020, and 2030. For each of these years, Pechan summed the total VMT for each county and then performed a linear interpolation between the 2000 and 2005 county-level VMT totals to estimate county-level 2002 VMT. Similarly, Pechan linearly interpolated the county-level VMT totals from 2010 and 2020 to obtain an estimate of the 2018 county-level VMT totals. Finally, for each of these four counties, Pechan divided the interpolated 2018 county-level VMT by the interpolated 2002 county-level VMT to calculate a 2002 to 2018 VMT growth factor. These county-level VMT growth factors were then applied to all road types and vehicle types within the corresponding county. These growth factors are as follows: 2.09 for Dallas County, 1.64 for Madison County, 1.48 for Polk County, and 1.64 for Warren County. Default VMT growth factors were used in all other Iowa counties.

ii. Minnesota

The Minnesota Department of Transportation (MnDOT) provided a series of historical annual VMT data from 1983 to 2003. From these data, Pechan conducted a set of regression analyses with the Minnesota historical VMT as the dependent variable, and historical Minnesota values (from REMI model incorporated into EGAS 5) for the following potential independent variables: year, driving age population, gasoline and oil expenditures, real disposable per capita income, and total output. Although population came in a close second, the variable with the best statistical fit was year. Pechan solved the resulting equation with values for year of 2002 and 2018 and computed the ratio of the 2018 equation value to the 2002 equation value. This resulted in 2002 to 2018 VMT growth factor of 1.37 that was applied Statewide to all road types and vehicle types.

iii. Oklahoma

The Oklahoma DEQ provided a spreadsheet containing State total VMT from 1983 through 2020. The VMT from 1983 through 2003 were daily Highway Performance Modeling System (HPMS) actual VMT totals. The 2004 through 2020 daily VMT totals were estimated by Oklahoma DEQ using linear regression based on the actual VMT data. From these data, Pechan estimated a 2002 to 2018 State-level VMT growth factor by dividing the projected 2018 daily VMT value by the 2002 Oklahoma HPMS daily VMT value. This resulted in a growth factor of 1.2754 and was applied Statewide to all road types and vehicle types.

iv. Texas

Pechan estimated VMT growth factors for the counties in the Austin and Dallas areas, based on publicly available data.

Pechan obtained VMT for the Austin area from August 2003 TCEQ-sponsored on-road mobile source emission inventories for the Austin/San Marcos Metropolitan Statistical Area. The following counties were included in these inventories: Bastrop, Caldwell, Hays, Travis, and Caldwell. For each of these counties, daily September VMT were provided for 1995, 1999, 2002, 2005, 2007, and 2012, with separate values for Monday through Thursday, Friday, Saturday, and Sunday. Pechan summed the VMT by county in each year to obtain total VMT for a week in September. Using the 2007 and 2012 weekly September VMT data, Pechan performed a linear extrapolation to estimate 2018 weekly September VMT. County-level VMT growth factors from 2002 to 2018 were then calculated by dividing the 2018 weekly September VMT by the 2002 weekly September VMT.

Pechan obtained VMT projection data for the Dallas area from the 2004 update to the Metropolitan Transportation Plan, prepared by the North Central Texas Council of Governments. This document included 1999 and 2025 VMT data for five individual counties (Dallas, Tarrant, Denton, Collin, and Rockwall) plus two additional area groups including two counties each (Ellis and Kaufman in one group and Johnson and Parker in another group). Pechan used linear interpolation to estimate 2002 and 2018 VMT data for each of these counties or county groups and then calculated the 2002 to 2018 VMT growth factors by dividing the estimated 2018 VMT by the estimated 2002 VMT.

Table II-23 summarizes the non-default VMT growth factors applied in the CENRAP States. All of these non-default growth factors were applied to all road types and vehicle types in that county.

Table II-23. 2002 to 2018 Non-Default VMT Growth Factors Applied in CENRAP States

State	County	2002 to 2018 VMT Growth Factor
Iowa	Dallas	2.09
	Madison	1.64
	Polk	1.48
	Warren	1.64
Minnesota	All	1.37
Oklahoma	All	1.28
Texas	Bastrop	1.62
	Caldwell	1.43
	Collin	1.85
	Dallas	1.32
	Denton	1.99
	Ellis	1.79
	Hays	1.44
	Johnson	1.75
	Kaufman	1.79
	Parker	1.75
	Rockwall	1.70
	Tarrant	1.47
	Travis	1.75
	Williamson	2.18

2. SMOKE MOBILE6 Inputs

Each SMOKE-formatted MOBILE6 input file represents a single representative MOBILE6 scenario for a specific county or group of counties. For each county or group of counties modeled, two SMOKE-formatted MOBILE6 files were prepared: one representing July conditions and one representing January conditions. Within SMOKE, the July input files will be used to model the ozone season months (i.e., May through September) and the January input files will be used to represent all other months. For counties with no State or local control programs and no locally-provided inputs, these MOBILE6 inputs primarily contain the calendar year being modeled (2018) and fuel input parameters for the season being modeled. Temperature data are also provided, but these are overridden in SMOKE by temperatures specific to the month being modeled. A simple SMOKE-formatted MOBILE6 input file for a county with no local inputs is shown below:

```
SCENARIO RECORD    : ARKANSAS COUNTY, AR - WINTER
CALENDAR YEAR      : 2018
EVALUATION MONTH   : 1
ALTITUDE           : 1
MIN/MAX TEMPERATURE: 50.0 70.0
FUEL RVP           : 13.0
FUEL PROGRAM       : 1
DIESEL SULFUR      : 15.0
OXYGENATED FUELS   : 0.500  0.001  0.006  0.001  1
PARTICULATE EF     : PMGZML.CSV PMGDR1.CSV PMGDR2.CSV PMDZML.CSV PMDDR1.CSV PMDDR2.CSV
```

Note that no speed information is included in this input file. The speed information is provided in the projected VMT files at the county/roadway type level of detail. In all cases, CALENDAR YEAR was set to 2018, ALTITUDE was set to "1" (i.e., low altitude), MIN/MAX TEMPERATURE was set as shown above (as dummy temperature values), DIESEL SULFUR was set to 15.0 (i.e., 15 ppm sulfur in the diesel fuel), and the PARTICULATE EF command was set using the files listed in the example above. The EVALUATION MONTH command was set to "1" for the January input files and to "2" for the July input files. The remaining commands listed in the example above (FUEL RVP, FUEL PROGRAM, ands OXYGENATED FUELS), as well as any additional commands needed, were set according to the specifics of the county or counties being modeled.

Note that the diesel sulfur input of 15 ppm sulfur in the diesel fuel represents the expected national diesel sulfur content in 2018. This reflects the requirements of the Federal heavy-duty vehicle/low sulfur diesel rulemaking. Other Federal control programs are included in the MOBILE6 defaults, with no additional inputs needed. This includes the emission standards associated with the heavy-duty vehicle rulemaking, the Tier 2 emission standards for light-duty vehicles and trucks, as well as all prior emission standards.

Optional local inputs that were included in the MOBILE6 files that are not related to control programs are the registration distributions and diesel sales fractions. The registration distributions (a distribution of registered vehicles by age for 16 vehicle types) used in the CENRAP 2002 base year modeling were used without change in the 2018 modeling. All CENRAP States except Arkansas has included registration distributions in the 2002 modeling.

The diesel sales fractions (the fraction of vehicles sales by model year that are diesel-fueled for 14 weight categories of vehicles) from 2002 were projected forward to 2018. To do this, the vehicles sales fractions listed for the 2002 model year were carried forward to all model years from 2003 to 2018. The diesel sales fractions values from the 1994 through 2002 model years, as listed in the 2002 diesel sales fractions files, were not changed. The diesel sales fractions from model years 1978 were removed from the files, as these model years are not needed in the 2018 calendar year modeling. Diesel sales fractions were provided in the 2002 CENRAP base year modeling for all CENRAP States except Arkansas and Texas.

A set of January and July SMOKE MOBILE6 input files were created for each group of counties with a unique combination of local inputs, fuels, and control programs. Thus, since Arkansas had supplied no local inputs, and there are no county-specific control programs in the State, a single set of MOBILE6 input files is used to model the entire State of Arkansas. In most of the other States, a single set of input files models a single county since most States provided county-specific registration distributions or diesel sales fraction data.

Area-specific control programs modeled in each State are described below.

a. Inspection and Maintenance and Anti-tampering Programs

Onroad vehicle inspection and maintenance (I/M) programs and/or anti-tampering programs (ATPs) are required in specific counties in Louisiana, Missouri, and Texas. Changes to these programs have occurred or will occur such that the versions needed for the 2002 modeling were updated to best reflect the programs expected to be in place in 2018.

i. Louisiana

The Louisiana I/M program applies to the 5-parish Baton Rouge ozone nonattainment area (Ascension Parish, East Baton Rouge Parish, Iberville Parish, Livingston Parish, and West Baton Rouge Parish). The specifics of this program, in MOBILE6 format, are shown in Figure II-1.

ii. Missouri

Missouri includes a basic I/M program in Franklin County, per State regulation 11 CSR 50-2.400 “Emission Test Procedures” and an enhanced I/M program in the remainder of the St. Louis area (St. Louis City, Jefferson County, St. Charles County, and St. Louis County), per State regulation 10 CSR10-5.380 “Motor Vehicle Emissions Inspection.” The specifics of the Franklin County program, in MOBILE6 format, are shown in Figure II-2. The St. Louis enhanced program is shown in Figure II-3.

iii. Texas

The Texas I/M program and ATP differ by the start date of the program in various county groups. In addition, the El Paso program is different from that in the other parts of the State. The Texas I/M program is defined in State regulation section 114.50 "Vehicle Emissions Inspection Requirements. The specifics of the Texas program, in MOBILE6 format, are shown in Figure II-4 for Harris, Dallas, and Tarrant Counties. The El Paso program is shown in Figure II-5. I/M inspections began in Collin and Denton Counties in 2002. This program is shown in Figure II-6. Testing began in 2003 for Brazoria, Ellis, Fort Bend, Galveston, Johnson, Kaufman, Montgomery, Parker, and Rockwall Counties. This program is shown in Figure II-7. Finally, testing is scheduled to begin in 2005 for the Austin area counties of Travis and Williamson. The characteristics of this program are shown in Figure II-8.

b. Gasoline Programs

The control programs modeled in the SMOKE MOBILE6 input files included the effects of several gasoline programs. Reformulated gasoline was modeled in the St. Louis, Missouri; Houston, Texas; and Dallas, Texas ozone nonattainment areas. The specific counties modeled with Federal reformulated gasoline are the same as those modeled with this program in the NONROAD model runs, as shown in Table II-11. No changes were expected in oxygenated fuel programs or inputs. Therefore, the MOBILE6 oxygenated fuel input parameters did not change from the 2002 base year modeling.

State-run low RVP gasoline control programs are in place in three of the CENRAP States: Kansas, Missouri, and Texas. These low RVP programs are not statewide, but are in specific counties. The Kansas and Missouri programs are in 1-hour ozone maintenance areas. The Texas program covers a broader area of the State. In addition to these State low RVP programs, the six-parish Baton Rouge ozone nonattainment area is subject to a 7.8 psi RVP maximum during the ozone season months, as regulated by the Federal RVP program for southern ozone nonattainment areas. Descriptions of the individual State low RVP programs are given below. Note that these RVP limits were applied to the nonroad gasoline engines covered in the NONROAD model, as well as onroad vehicles, for the counties and months discussed below, and this information was summarized in Table II-12.

i. Kansas

The Kansas low RVP program is specified under Section 28-19-719 “Fuel Volatility” of the Kansas Air Quality Regulations and applies in Johnson and Wyandotte Counties. These two counties are part of the Kansas City ozone maintenance area. This regulation specifies that gasoline dispensed for use in motor vehicles in Johnson and Wyandotte Counties not exceed an RVP of 7.0 pounds per square inch (psi). Gasoline containing between 9 and 10 percent ethanol by volume is limited to an RVP of 8.0 psi. These regulations are in effect from June 1 through September 15 of each year, starting in 2001. To account for the time needed for individual gasoline stations to comply with these limits, the low RVP program is modeled from May through September in the MOBILE6 SMOKE input files.

ii. Missouri

The Missouri low RVP program is specified under Section 10-2.330 “Control of Gasoline Reid Vapor Pressure” of the Missouri Code of State Regulations for the Air Conservation Commission and applies in Clay, Platte, and Jackson Counties. These counties are part of the Kansas City ozone maintenance area. This regulation specifies that gasoline dispensed for use in motor vehicles in Clay, Platte, and Jackson Counties not exceed an RVP of 7.0 psi. Gasoline containing between 9 and 10 percent ethanol by volume is limited to an RVP of 8.0 psi. These regulations are in effect from June 1 through September 15 of each year, starting in 2001. To account for the time needed for individual gasoline stations to comply with these limits, the low RVP program is modeled from May through September in the MOBILE6 SMOKE input files.

iii. Texas

The Texas low RVP program is specified under Section 114.301 through 114.309 “Low Emission Fuels, Division 1: Gasoline Volatility” of the Texas Natural Resource Conservation Commission regulations and applies in a 95-county area of eastern Texas. This area excludes the eastern Texas counties in the Dallas and Houston area that are included in the Federal reformulated gasoline program. This regulation specifies that gasoline dispensed for use in the 95 affected counties not exceed an RVP of 7.8 psi. These regulations are in effect at gasoline dispensing facilities from June 1 through October 1 of each year, beginning in 2001. To account for the time needed for individual gasoline stations to comply with these limits, the low RVP program is modeled from May through September in the MOBILE6 SMOKE input files.

A separate low RVP program is in place in El Paso County. Under this program, gasoline dispensed in El Paso County is limited to an RVP of 7.0 psi from June 1 through September 16. This program began in 1996. To account for the time needed for individual gasoline stations to comply with these limits, the low RVP program is modeled from May through September in the MOBILE6 SMOKE input files.

CHAPTER III. DEVELOPMENT OF DATA FOR AREAS OUTSIDE OF THE CENRAP STATES

A. WRAP

The Western Regional Air Partnership (WRAP) includes all of the States west of the CENRAP region. WRAP's current schedule for preparing new emission projections for its States did not include any new information by March 2005, so the previous WRAP 2018 emission forecasts will be used as the basis for CENRAP's projection year emissions modeling. The existing WRAP 2018 emission forecasts are made from a 1996 base year. The CENRAP emission modelers already have access to these WRAP emission inventory projection files, so Pechan did not expend any further effort in preparing or modifying the WRAP emission projection data.

B. VISTAS

The Visibility Improvement State and Tribal Association of the Southeast (VISTAS) includes the States of Alabama, Florida, Georgia, Kentucky, Mississippi, North Carolina, South Carolina, Tennessee, Virginia, and West Virginia. VISTAS had recently completed 2018 emission projections for its States in March 2005. VISTAS agreed that CENRAP may use the 2018 SMOKE-ready emission modeling files that VISTAS developed for its States once all QA has been completed on these files. Because the CENRAP emission modelers are the same as those performing the emission modeling for VISTAS, Pechan did not expend any further effort in preparing or modifying the VISTAS emission inventory.

For the EGU sector, CENRAP determined that it would be best to use a consistent IPM data set for all of the non-WRAP States. Therefore, for the EGU sector, the VISTAS EGU data will be replaced by the EGU data from the summer 2005 IPM projections.

C. MRPO

The Midwest Regional Planning Organization (MRPO) includes the States of Illinois, Indiana, Michigan, Ohio, and Wisconsin. Pechan developed growth factors for the point and area source emissions for the MRPO States as discussed in section II.A of this document. Pechan obtained the mobile source inputs for the MRPO States from 2018 modeling prepared by VISTAS, with the permission of both VISTAS and MRPO. These are the inputs that were used in VISTAS 2018 modeling for these States, with inputs provided by MRPO States. Pechan prepared point and area source control factors, based on projection year modeling we had prepared earlier for MRPO. The emission inventory file for 2018 for the NONROAD model categories was based on interpolating the 2015 and 2020 nonroad emission inventories prepared by EPA in support of the Clean Air Interstate Rule in 2004 (EPA, 2004c). Emissions from the MRPO States for the EGU sector will be obtained by CENRAP from the summer 2005 IPM runs.

D. MANE-VU

The Mid-Atlantic/Northeast Visibility Union (MANE-VU) MRPO includes the States of Connecticut, Delaware, Maine, Maryland, Massachusetts, New Hampshire, New Jersey, New York, Pennsylvania, Rhode Island, and Vermont, and the District of Columbia. For the MANE-VU States, Pechan used the point and area source growth factors developed for the MRPO States as discussed in section II.A of this document. Pechan obtained the mobile source inputs for the MANE-VU States from the 2018 modeling prepared by VISTAS, as discussed above for MRPO. These are the inputs that were used in VISTAS 2018 modeling for the MANE-VU States. Pechan prepared point and area source control factors, based on projection year modeling we had prepared earlier for MRPO that include the MANE-VU States. The emission inventory file for 2018 for the NONROAD model categories was based on interpolating the 2015 and 2020 nonroad emission inventories prepared by EPA in support of the Clean Air Interstate Rule in 2004 (EPA, 2004c). Emissions from the MRPO States for the EGU sector will be obtained by CENRAP from the summer 2005 IPM runs.

E. CANADA

Available emission data sets for Canada are currently limited to historical emission years--1995 and 2000. EPA and LADCO/MRPO are using these inventories to estimate current and future year emissions for these provinces. It is our understanding that LADCO is using/planning to use 1995 point source emission estimates and 2000 onroad/off-road/area source emission estimates to estimate Canadian emissions for their modeling domain. (The 2000 point source emissions data are not being used because of confidentiality limitations.) The 2000 Canadian emission data sets for the three nonproprietary sectors (non-point/area, nonroad mobile, and onroad mobile) are available at: http://www.epa.gov/ttn/chief/net/canada.html#data. This file contains information in both dBaseIV and SMOKE IDA format.

While we know that Environment Canada compiles emission projections on a regular basis to support the development of Federal and provincial emission control strategies, it is not expected that Environment Canada would be able to provide growth and control factors on a timely basis for this CENRAP project. Pechan recommended that CENRAP use the base year 1995 and 2000 Canadian emissions data without adjustments for all future year model simulations. The CENRAP emission modelers already have access to these Canadian emission inventory files, so Pechan did not expend any further effort in preparing or modifying the Canadian emission inventory.

F. MEXICO

The emissions inventory base year for Mexico is for 1999, from the BRAVO study. Inventories for the years 2002 and 2012 were also estimated in order to understand how growth and existing control strategies may impact future emissions. Currently, the 1999 emission inventory is available, but the emission databases for the other years are not. Moreover, the point source database will most likely be proprietary, and could require signing a non-disclosure agreement for access. Pechan has recommended, and CENRAP has agreed, that the 1999 Mexican emission database be used as is for the CENRAP 2018 modeling, due to the uncertainty inherent

in applying growth and control factors to this inventory. The CENRAP emission modelers already have access to these Mexican emission inventory files, so Pechan did not expend any further effort in preparing or modifying the 1999 Mexican emission inventory.

CHAPTER IV. ISSUES OF CONCERN
